Reel duplication of the whole or of any part of this film is prohibited. In lieu of transcripts, however, enlarged photocopies of selected items contained on these reels may be made in order to facilitate research.

A Note on the Sources

The pages which were microfilmed for this collection are in generally good condition in the original. There are some pages, however, which due to age are lighter than normal. Additionally, because some volumes are very large and have been bound tightly and cannot be unbound, there are intermittent occurrences of slight distortion of the edges of a small percentage of the pages. We have made every technical effort to ensure complete legibility of each and every page.

surprise, and we are glad to remember that it was not an Englishman, nor even a Scotchman, who showed such supreme incapacity for seeing the absurdity of his language. He to Englishmen, however, we are now briefly addressing ourselves, and they cannot claim any immunity from sharp criticism so long as they despise the ordinary aids to lucid and dignified explanation which the long-suffering student has a right to demand of them.

CORRESPONDENCE.

CARBONS AND DIFFUSION APPARATUS FOR THE ELECTRIC LIGHT.

(CONTINUED.)

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Very few words will be sufficient to describe the improvements which have been made since 1846, when the first patent for the manufacture of carbon rods for electric lighting was taken out by Messrs. Greener and Staite, as raw material carbon of gas retorts, foundry coke, lampblack, and charcoal have been used, and as agglomerating mediums, sugar, gummes, molasses, starch, glues, &c., in fact, any kind of agglutinating materials have been all patented over and over again, but with no improvement in the ultimate product. Within the last eighteen months or two powerful potents were taken out by different persons, but there is absolutely nothing new in them except the names of the patentees, who (or some of them, at all events) appear to have rushed into the manufacture of carbon rods as soon as they heard that possibly the electric light was coming on, trusting that some day the public might be dazzled into subscribing capital towards the formation of a company of some sort to work their so-called patents. Some patentees have introduced wires of copper or of iron into the interior of the carbon rods, with what result it is needless to inquire, as a knowledge of the first rudiments of chemistry on the one hand, and of the laws of expansion on the other, easily disposes of the value of the introduction. Some others, like Mr. E. Hedges, advocate the introduction of certain oxydes likely to impart to the light a certain colour to hide the natural colour of the electric arc until the public get accustomed to its brilliant whiteness, or, in other words, Mr. Hedges, and those who follow the same principle, propose simply to obliterate the electric light: but of real, genuine improvements, beyond those introduced by Mr. Gaudais, and attempted by Mr. Jaquelin, there have been none. It may be the quantity of these carbon rods actually required, and probably to be required for some years to come, is too small to warrant any large outlay of money with a view to amply secure the manufacture of the best article for the future. Probably in time to come, however, the best carbons will be manufactured on a process based on that of Mr. Jaquelin. As I said in my last, Mr. Jaquelin based his manufacture of carbon on a sound theory. Not being able to obtain carbon in a fused or dissolved state, he took the only course open to him to arrive at a perfect conglomeration of the molecules of carbon just at the time this material is disengaged from some of the gaseous compounds it forms with hydrogen. The plan followed by Mr. Jaquelin unfortunately necessitates the mechanical cutting of the rods from the block of carbon he produces, and this entails no small expense, and constitutes no little drawback. A modification of his process or plan is, however, possible, and by a very simple arrangement the carbon rods, after having been moulded, dried, and baked once, can be completed by following part of Mr. Jaquelin's valuable discovery. Moreover, Mr. Jaquelin manufactured the hydrocarbides he required direct from the coal, and having eliminated from them the carbon they can part with, used them no more; I use them again, and make them take up again as much carbon as they left behind in the rod they had to pass through; by such means a carbon rod of perfect compactness and homogeneity is obtained at less cost and labour than by the ordinary processes.

DIFFUSION.—The peculiarity of the electric light is that it is entirely composed of sharp, well-defined rays, and hence the necessity of diffusing that fast spending light, or, to better perhaps, express my meaning, of fusing together all the rays into a compact luminous focus, something similar to what is naturally produced in the flame of gas, or petroleum oil. It seems to me that all the different contrivances hitherto termed "diffusers" (permit me to use the term) are wrongly named;

MR. EDISON'S LIGHT.

What Two Scientific Men Who Have Seen Only Electric Lights Say.

Although many of the visitors to Menlo Park are unacquainted with what has been heretofore accomplished in electric lighting, by far the greatest number are well informed on the subject, and it is interesting to hear them compare Mr. Edison's lights with the Gramme, Siemens and Wallace lights. Said one last evening: "In the Avenue de l'Opera, in Paris, recently, I saw ten electric lights on one circuit. They were on the voltaic arc principle, and the fact that ten lights could be generated by one dynamo machine was considered a marvel. The Jablochkoff candle was then in vogue, and I saw that it was falsified. Parts of the apparatus were brilliantly lighted, while other parts were not in even shade. It was easily seen that for the present, together with the cost of the lamps, this system was impracticable."

Much amusement was created in Menlo Park by an article recently published in a morning paper stating that Mr. Edison's 1,000 candle lights were a failure because none of them was of greater intensity than an ordinary gas jet. Mr. Edison explained, however, that it is easy enough to multiply small units into large ones. The object is to reduce and subdivide the light for practical purposes.

It has been objected by critics that the difference of potential between the wires leading to and returning between points remote would render it in an economy where the wires terminate, and that the loss would be great. Mr. Edison explained, however, the fact that the arc without has a constant pressure of fourteen pounds to the square inch, the Gramme lights have two pounds pressure, the Siemens lights twenty pounds. The difference in pressure between the two points can be varied to any extent necessary. Mr. Edison has succeeded in sinking an insulated wire in the earth without loss of current.

The experiments with a polished platinum bar the Electric Light stock had dropped to $1,500 a share, and the Edison Electric Light stock sold yesterday for as much as $3,000 a share, and the sales were large. The sales of the Edison stock at auction yesterday were at the rate of 3,000 shares per day.

LONDON, Jan. 5.—The Paris correspondent of the Standard telegraphs: "The power of Edison's discovery in electric lighting has produced great excitement in scientific circles here. An eminent French authority on electric science, writes to the Temps, saying that Edison's lamp is not new, and asserts that until the contrary is proved he considers the Edison discovery a myth."

1495. "Electric lamps." A. V. Newton. (A communication from F. Tommasi.) Dated October 30, '80. (In communicating a pedestal lamp a carbon block, used, carried by central rod for a series of carbon electrodes to burn together. These carbon electrodes, about in mercury trough, which, being brought upwards a common centre.)

fait connaître la forme primitive[1] et qui s'est présentée au public parisien il y a un mois, au moment des expériences d'éclairage électrique du foyer de l'Opéra, sous une forme nouvelle qui constitue, à notre point de vue, un réel progrès.

La lampe Werdermann, par son principe, participe à la fois de l'éclairage par incandescence et de l'éclairage par l'arc voltaïque; elle constitue donc un système intermédiaire qui doit remplir des conditions spéciales. Dans le modèle représenté ci-dessous (fig. 1) l'inventeur s'est attaché à régler la pression du contact latéral sur la tige de charbon

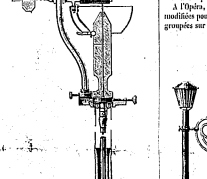

Fig. 1. — Nouvelle lampe électrique de M. Werdermann.

d'après la pression que cette tige exerce sur le disque supérieur.

Pour cela le disque de charbon supérieur est placé sur un fléau dont on règle l'équilibre par un poids à vis.

Ce fléau porte un petit levier, placé à l'intérieur du globe, et qui vient exercer sur le contact latéral mobile du charbon une pression d'autant plus grande que la pression de ce charbon fixe[2] est elle-même plus grande; cette pression s'oppose au mouvement ascensionnel de la tige de charbon.

Il y a donc là une sorte de frein dont l'équilibre dépend du réglage primitif à l'aide de contrepoids. A mesure que le charbon s'use, la pression sur le disque diminue, le contact latéral se desserre un peu et permet le mouvement ascendant de la tige de charbon. Cette disposition qui permet de *très légers* contacts entre le disque et la tige, fait qu'il n'y a jamais rupture de la pointe, mais usure régulière, et par suite une grande fixité de la lumière, ce que tout le monde a pu constater à l'Opéra.

Comme plusieurs lampes sont montées en tension sur le même circuit, il faut que, si l'une d'elle s'éteint, elle soit aussitôt mise en dehors du circuit pour ne pas éteindre les autres.

Ce résultat est obtenu par le levier coudé qui sert à presser sur le contact latéral. Quand la tige ne vient plus appuyer contre le disque, ce disque descend et le levier vient buter contre un arrêt métallique qui établit une communication directe et met la lampe hors du circuit.

A l'Opéra, les 42 lampes Werdermann ont pu modifiées pour le cas spécial par M. Napoli étaient groupées sur quatre lustres. Elles étaient alimentées

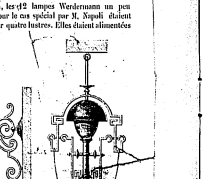

Fig. 2 et 3. — Appliqué et suspension de M. Werdermann pour l'éclairage électrique.

par 2 machines Gramme, chacune de ces machines ayant dans son circuit six lampes montées en tension. A défaut de mesures photométriques, il nous est absolument impossible de nous prononcer sur la valeur économique du système Werdermann, regrettant malheureusement trop fréquent à une époque où toute invention se ramène à une question de francs et de centimes. M. Werdermann se propose d'appliquer ses appareils à l'éclairage domestique. Nous représentons, figure 3, une suspension et figure 2 une appliqué qui montrent que ces appareils se prêtent à un effet décoratif, bien que ces modèles laissent un peu à désirer au point de vue artistique.

Le Propriétaire-Gérant : G. TISSANDIER.

[1] Voy. n° 297 du 30 novembre 1878, p. 417.

A NEW ELECTRIC LAMP.—An electric lamp for use in workshops, railway stations, mines, collieries, and the like, the invention of Mr. C. W. Harrison, of Queen Victoria Street, London, is being brought out by the Sun Electric Light Company, at their experimental works, No. 80, Grey's-inn-road, London. In this lamp carbon rods 3/8 in. in diameter, and placed vertically, are used, the positive being the top carbon and the negative the bottom one. The adjustment is stated to be automatic and not to consist of weights, springs, or any similar clockwork arrangement whatever. What this adjustment does consist of, however, is known only to the inventor at present, particulars being withheld from the public in consequence of the foreign patents not having been quite completed. The light is a good, strong, and steady one, and on the light being extinguished through any accident, contact is instantly renewed. The light is about to be employed at collieries near Manchester and in South Yorkshire. The inventor claims to have solved the questions of divisibility of the current and modification of the light, and he proposes, after the foreign patents shall have been secured, to exhibit a number of lamps suitable for public and private purposes. Drawings were shown illustrating the principles of the proposed method of street illumination. This consists in the point of light being placed in the base of the lamp standard and directed up the interior of the lamp post, on the top of which is placed a circular reflector, by means of which the light will be reflected around. There were other modifications shown which will be best described when the principles of the invention are made known. The company are manufacturing their own carbons, which are understood to be made by a special process to insure uniformity in composition and as to conduce to steadiness of the light.

OBSTACLES TO THE SUCCESS OF EDISON'S SYSTEM.

CLEVELAND, OHIO, Feb. 3.—A well-known electrician of this city, who recently returned from a visit to Edison's laboratory at Menlo Park, has been indulging in some severe criticisms on the inventor and his work with regard to electric lighting. As these comments are in great measure based on statements of alleged facts, they are falsely and fatally inspired into. As a result of his inquiries, which were very thorough, he asserts that Edison has simply converted a lot of scientific humbug with the design of dazzling the public, which has forgotten the experiments of Sir Humphrey Davy and other that attracted so much attention thirty years ago. Taking up seriatim the claims of the inventor, or put forward in his behalf, said he, there comes first the assertion that the carbon horseshoe would last indefinitely without there being any indication of its differing from the horseshoe carbon employed before. It was well known before incandescent carbon, even in superficial vacuum, if heated sufficiently to be of any value as a light-producing agent, could last but a short time, owing to a peculiar disintegration of the material, the cause of which has never been satisfactorily determined. It seems that Edison, in order to make his carbon last somewhat less a reasonable length of time, heated them to a comparatively low temperature only, thus sacrificing most of their light-producing power in order to add to their durability, which was thereby still limited. In this one point of want of durability, which has wrecked all previous experimenters during the past 24 years, he appears to have made no advance whatever. It has been assumed by Edison and the public that this lamp would give a decrease in the way of durability the problem of economical electric lighting by the incandescent plan would be solved. This is far from being the case. Success would be as hopelessly far off as ever. A question of economy would at once arise, and here the real difficulty will begin. Edison has carefully ignored or avoided this point, undoubtedly understanding fully where its discussion would land him. He called his lights 10 candle-power each. Even if they were of this size, no one would think of accepting one in place of a 16-candle gas-burner. But the fact is, they were by no means of 10 candle-power each, as any experienced observer could see at a glance, and as photometric measurements appear to have been made in the laboratory. Moreover, the light differs greatly at different aspects. For instance, when the edge of the horseshoe is presented, the light evolved is vastly less than when the side is viewed. Even granting 10 candles for the side of the horseshoe, the light from the edge is noticeably very much less. Mr. Edison claimed to produce four or five lights with a consumption of one horse-power in driving his generators, but promised to so improve his apparatus as to get 8 or 10 lights per horse-power. Even assuming those latter figures to have been attained, the hopelessness of the affair in an economic sense is apparent to any thinking person. But, in point of fact, he has failed if he can get more than two, or possibly three, of these small lights per horse-power under the best management.

It was perfectly apparent to this gentleman that, from the size of the belts carrying the power, from the rapidity of the revolution of the machines, and from the heating of the armatures and field magnets, each machine was absorbing from five to seven horse-power; and as he has never had to exceed 50 lights burning at one time it is evident that he is not now getting with his present apparatus more than three or, at the outside, four lights per horse-power.

The absurdity of the claims made for the so-called Edison governor, with which the electric current for Edison's lights has been produced, has been discussed and made sufficiently apparent by many scientific writers during the past few months. A critical investigation of this governor reveals the fact that it is a rather poor form of the well-known Siemens machine without any novel or additional feature.

Much has been said in connection with Edison's lamp about the great convenience of the well-known Sprengel air-pump (which he uses to exhaust the air from his lamp bulbs), by reason of which the time required to effect the exhaustion was reduced from 40 odd hours to 25 minutes, and through which the extraordinarily perfect vacuum of a millionth atmosphere was attained. In *Beerbauer's Philosophy*—1873, page 198—Dr. Sprengel, the inventor of the Sprengel pump, says:—"From 20 to 25 minutes are required to exhaust a receiver of the capacity of half a litre." This is a much larger receiver than the Edison lamp bulb. Again: "By this instrument air has been reduced to one thirteen hundred thousandth atmospheric density, and this average exhaustion attainable by its use is about one millionth." It is easy to see where Edison borrowed his air-pump thunder.

The author of the article goes on to discuss in great detail the cost of lighting New York on Edison's system, and concludes that the cost of each light would, by this estimate, be 21 dollars a year. It would not be equal to the light furnished by a four-foot burner. At 1 dollar per 1,000 for gas, the average annual cost of a single burner to the consumer is 2 dollars or 2 dollars 50 cents at 2 dollars per 1,000. If gas were sold at 10 per cent. profit, it could be delivered in the laboratory for 40 cents per 1,000. The actual cost to the gas companies is less than 30 cents. Granting all his claims, Edison's electric light would entail an expense equal to that of a gaslight of greater brilliancy at 2 dollars 50 cents per 1,000, while the gas companies would make more money than the Electric Light Company, and sell it for 40 cents per 1,000.

Another point that does not seem to have been made clear by Mr. Edison, or at least about which he has said little, is the necessity for some automatic means of regulating the current delivered by his generators, so that sudden and great changes in the number of lamps being used at any time shall not affect the uniform working of his system. For instance, in lighting a large hotel, it would be necessary to have a sufficient amount of the current provided to maintain, say 1 thousand lamps at one time, at 7 o'clock in the evening. Two or three hours later, perhaps, only half this number of lamps would be burning, and after midnight possibly not one-tenth. It will be at once evident that for the proper operation of the Edison system in such places, an automatic regulator of the quantity of current must be provided which will follow accurately, and with the utmost certainty, these changes in the number of lamps burning, so that when all are burning each one will give full light, and when one-tenth only are burning each one will give only its normal light. So far as the public knows, no arrangement whatever has been provided to meet this imperative necessity in such a system. In the recent article in *Scribner's Monthly*, written by one of Mr. Edison's employés, and accompanied by lithographic sketches, this vital point is not even mentioned. To those conversant with the subject, it does not seem possible to provide practically for this difficulty. At present, at Mr. Edison's, a young man is stationed in the vicinity of the apparatus with his eye on the Thomson galvanometer, prepared to throw into the circuit more or less artificial resistance to provide for any changes of current caused by the increase or diminution in the number of lamps burning.—*New York Times*, Feb. 7.

CHRONIQUE

La lumière électrique et les végétaux. — L'institution de la *Royal Society d'Angleterre* vient d'ins appelle sur une découverte assez singulière, qui sera sans doute utilisée pour l'horticulture. Il s'agit de l'influence de la lumière électrique sur les végétaux. A la suite d'expériences faites pendant plusieurs mois par le docteur Siemens aux environs de Londres, il a été reconnu que les plantes et les fleurs exposées pendant la nuit à la lumière électrique poussaient et prospéraient beaucoup mieux que celles qu'on laisse simplement exposées à la lumière du jour et qui restent la nuit dans l'obscurité. Pour montrer combien l'influence de la lumière électrique se fait sentir rapidement sur les fleurs, le docteur Siemens a placé sur une table, dans la salle de conférences de la *Royal Society*, un pot de tulipes en bouton; ces tulipes

ont été soumises aux rayons d'une lampe électrique. Au bout de quarante minutes, elles étaient complétement épanouies.

ANDRÉ'S ELECTRIC LIGHT FOR MANSIONS.

While the attention of the public is directed to the numerous laboratory of Menlo Park for the advent of the coming electric light which is to astonish the world, and eclipse alike the spirits of gas-shareholders and the dividends which yields them their fat dividends, and while it is directed there, then far at least in vain, a great deal of quiet, successful work is being done and progress made in practical electric lighting, both in England and the Continent. Although we are not in a fortunate circumstance for our inventors that they are not subjected in this country to the blustery of the Press, and do not, like Mr. Edison, lose the sweet inspiration of secret working which flatters success and revolution alone can give. They are not also forced to count their chickens before they are hatched, and trumpet forth what they mean to do before they can be sure of doing it. The true development of an invention is seclusion, secrecy, and alone can still be followed out. If it is successful, a rush reward is earned; while if it fails, the worker does not incur any opprobrium for announcing results which could not be achieved.

The electric lamp of Professor André has not been often brought before the notice of the public. It is a lamp on which the inventor has spent a vast deal of labour and ingenuity, and one which promises to take a high place in the electric lighting of the immediate future. It is a small lamp designed for lighting private dwellings, shops, and factories, and is in this respect unlike the ordinary lamps of Siemens, Rapieff, and Jablochkoff, now in vogue, for it can also be made to give a very intense light. We recently described his first form of the lamp in *The Electrician*, page 174, Vol. III., but its efficiency has been much improved of late by several minor improvements. It may be remembered that it is based on the incandescent principle, and consists of several pencils of carbon enclosed in an air-tight glass cylinder, which forms the globe of the lamp. The pencils are placed vertically, and their points rest on a copper electrode in the bottom of the lamp. When the current is let on there is electrified points glow with great brilliance. The light lasts for many hours, because the carbons are very slowly consumed one after another in the carbonic acid gas which the air within the vessel is converted into after a short burning. Generally speaking, M. André's lamp comes between the incandescent electric lamps of Lodigrin and Swyne-Mann, which consist of a solid rod of carbon wholly heated by the passage of a current in a glass vessel filled with nitrogen, and the incandescent lamps of Regnier and Werdermann, which consist of incandescent carbon points burning free in air. The multiple points, the solid copper electrode for all the carbons to burn from, the electro-magnetic regulator, in short, the whole arrangements of the lamp are peculiar to M. André, and it must be confessed that the idea of placing the incandescent points in an atmosphere of carbonic acid, which is mostly formed by the action of the lamp itself, and, at the same time, is so essential to protect the fine carbons from unnecessary waste, is a happy and important one, though not altogether new.

The proof of an invention lies, however, in its practice, and M. André's lamp has now earned a fair title to public consideration. An exhibition of his system of electric lighting for mansions and dwelling houses came off at Stafford House on the evening of January 26, in the presence of the Prince of Wales, the Duke and Duchess of Sutherland, Sir Frederick Leighton, and several other gentlemen. The first experiment was made with six lamps of 75 candle-power each, in circuit with 1,000 yards of cable, and fed by one small Gramme machine; the second was made with 14 lamps of 70 candle-power each, in the same circuit; the third, of 70 lamps of 50 candles each, in a circuit of 2,500 yards, fed by the same machine; and lastly 30 lamps of 25 candles each, in the same circuit of 2,500 yards, and fed by the same machine. The power absorbed was from 1-3 to 1-6 horse-power per lamp.

The lantern ceiling of the grand staircase was lighted up brilliantly, clearly showing from below with very fine effect the splendid decorations overhead at a height of from 60 to 80 feet.

The dining rooms, drawing rooms, and boudoir were also lighted up with lamps, harmonising in general with white, pink, and yellow tissue paper, which produced a most agreeable, soft, and steady light, and when it was required to illuminate the pictures on the walls these tissues were removed so as to throw the unclouded effulgence of the lamps upon them. His Royal Highness the Prince of Wales was, we believe, greatly pleased with the light, and told Professor André that it was the best display of electric lighting he had yet seen. The apartments used at Stafford House has now been removed to the country mansion of Mr. Edward Easton, C.E., who is associated with M. André in the extensive development of the lamp, and will there be permanently installed as the model, to be shown the public, of André's system of domestic electric lighting. It is, we think, to be regretted that M. André should have chosen so inconvenient a place to exhibit his system, but probably he will also arrange to show it in operation in the metropolis itself."

The new lamp is not, of course, to be confined to dwellinghouses, or fiery mines, but is also especially adapted to mills, manufactories, and other large works. The North Shore Corporation, near Liverpool, have also been lighted by them, and the Mills, near Liverpool, have also been lighted by them, and the Liverpool Corporation, who have purchased an Act of Parliament to light the borough of Liverpool by means of electricity, mean to light the borough of Liverpool by means of electricity, are at present considering its advantages for the purpose of lighting streets.

[The above article was crowded out of our last issue, and since then we have seen an improvement which, to our mind, renders this lamp the best that has, as yet, been invented. This improvement has been made and carried out by the Hon R. Brougham, and will be described and illustrated next week.—Ed. E.]

SWAN'S ELECTRIC LAMP.

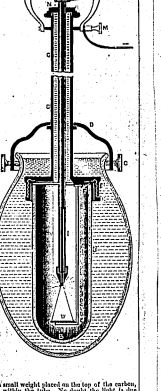
Swan's Electric Lamp.—Soon, the archipelago of Edison's carbonated lamp, has had his researches interrupted for a time by a disastrous fire. His engine and magneto-electric machines escaped, though most of his lamps and other appliances suffered. He is now aiming at the production of a permanent lamp on the incandescent principle.

THE ANDRÉ-BROUGHAM ELECTRIC LAMP.

The accompanying engraving is a perspective view, partly in section, of the lamp as it will be exhibited at Wells some other electric-light lamps have been. Investing lamps on paper Prof. André has been quietly pursuing his way, and now, with the assistance of the Hon. R. F. D. Brougham, he has evolved a lamp which by common consent is considered the best that has yet been. We take the following description from the *Engineer*:—

The value of the improvements which we have to note when we state that it reduces the carbon consumption to about 1000th per hour, whilst a similar carbon burns in the lamp then in the electric lamps burns about 6in. per hour, the cost in carbons being reduced from 1-20th of what it would be in an ordinary lamp. This is, probably, a maximum reduction, but the carbons in ordinary incandescent lamps use of a large glass vessel, fitted with the André-Brougham lamp being only 5cm. diameter.

The improvement consists in surrounding the lamp, or a portion of it, with a separate vessel of glass containing water or some other suitable liquid. In the accompanying diagram B B D is the glass globe of the lamp, and A A the vessel containing round containing the liquid. The shape or these vessels is immaterial. It may, perhaps, conduce to simplicity if the lamp is first described. Two concentric tubes (G G, I I) arrangented by a non-conductor, such as plaster of Paris. These tubes are connected to the two terminals of the circuit by the wires N and M. The tube G G forms a kind of electrical contact with the platinum stopped piece of metal W. The lower tube, I, contains the carbon rod, which rests upon the metallic wedge and falls down by its own weight, and that



of a small weight placed on the top of the carbon, but within the tube. No doubt the light is due partially to incandescence of the carbon, and partially to the formation of an arc. The cap, on the top of the tube O O, through which the carbon passes, is made of some non-conducting material. Through the top of the lamp globe B B B is a metal cylinder to be screwed into the corresponding cylindrical P P. The ring E E has a sharp edge at its top, whilst F F F has a corresponding recess. Between the two is an india-rubber washer F F, so that on screwing E E the chamber is pressed into the recess in F F F,

and a good watertight joint made. The lamp is filled with a cap, D D, to which, by means of binding screws G G and clamps, the vessel A A is fixed. This vessel is partially filled with water or other liquid, and the cap D D screwed down. The liquid rises above the top of the lamp globe, and the possession of air into the lamp an impossibility. So long as the lamp B B is heated to nearly 212 atmospheric air can enter the lamp globe B, a tight joint is obtained, and at the same time the heat from the lamp is carried off or dispersed, and the light more or less diffused.

THE WERDERMANN ELECTRIC LIGHT.

At the time when new systems of electric lighting were being introduced to the public in some what more rapid succession than they are at present, and which was about eighteen months since, we described, amongst others, the Werdermann light.* As we stated at the time, this light, although then not quite perfected as regards details, was one of considerable promise, and the period intervening between our previous notice and the present one has been advantageously occupied in working out its details to a very successful issue. Several modifications and improvements have been introduced in the system, which have rendered it in many respects a much more practical means of illumination than it previously was. Having recently been afforded the opportunity of inspecting the Werdermann Light in its improved condition, we propose placing particulars before our readers. We may premise that the demonstration was carried out at the London and wharf of Messrs. Rownson, Drew and Co., Upper Ground Street, Blackfriars Bridge, where one of these lights have been in successful use for somelittle time past. The demonstration took place in the presence of a number of scientific gentlemen and others interested in the question. It was conducted by Mr. Henry F. Joel, C.E., on behalf of the Signal Engineering Company, of 171, Queen Victoria Street, London, and was in every way a success.

In order to render clear to our readers the improvements that have been made in the system it will be best for us to describe it briefly as it existed at the date of our previous notice. It will doubtless be remembered that as originally constructed, the lamp consisted of a carbon pencil placed vertically point upwards and impinging upon the underside of a disc of carbon placed horizontally, and forming the negative electrode of the lamp. The disc was about 2 inches in diameter and 1 inch in thickness, the carbon pencil being rather more than one-eighth of an inch in diameter and of any convenient length, about 18 inches being the normal length adopted. The pencil was fed vertically under the disc in a guide, its lower end being fitted in a small holder in which a piece of fine cords were attached. These cords were led up over pulleys and down again to a counterbalance weight, and as the carbon rod was free to move in its guide in point was always held up against the underside of the disc with a gentle pressure. By this means the consumption of the carbon rod was uniformly and easily followed up. The same general principles and arrangements are preserved in the improved form of Werdermann light, its details only having been modified. The carbon pencil, instead of being a still divided, and is conducted to the lamps through a main cable, but without the branches leading to each lamp which were formerly adopted. There is, too, still the power of extinguishing any one or more lamps of the series without affecting the rest. The first point of departure is the substitution of a disc of copper for that of carbon, which was formerly used, and which answers its intended purpose equally as well as the carbon electrode. It is of the same diameter as was the carbon disc; but, unlike its predecessor, it is not consumed, while it produces an equally effective light. The carbon pencil impinges upon its underside as it did on the under side of the carbon disc. It will be seen that by this arrangement Mr. Werdermann has been the first to depart from the usual track in that his electrodes are always in close contact. He has discarded the electric arc space, not deeming it essential that a certain definite

interval should exist between the carbons, and he thereby produces what to all intents and purposes is a light of incandescence.

The next important feature is a new automatic arrangement, by means of which the carbons, in riding, regulate the contact pressure on itself. To this end, the copper disc is made movable, and capable of being eased upwards by the carbon beneath it. The copper disc is hinged or pivoted so as to slightly overbalance at the foot, where it impinges upon the carbon pencil. Attached to the rear of the disc is a flat spring which is pressed against one side of the copper nipples, through which the carbon pencil passes, by the upward pressure of the pencil acting upon the disc, the pressure of the pencil acting upon the disc, the pressure of the pencil acting upon the disc, the

ELECTRIC LIGHTING.

SOME important additional experiments have been carried out in connection with the electric lighting by Mr. Hedges Eyre Johnson-Jablochkoff system of electric lighting at Chatham Dockyard, "They were conducted at the Victoria Station of the London, Chatham and Dover Railway, where the offices of the Metropolitan District Railway, where the Jablochkoff system of electric lighting was introduced about two years." About that period towards the close of last year, Mr. Berly had the two rails of the up-line connected together by a "copper wire (insulated), both ends of Charing Cross and at Victoria Stations. He also had the two rails of the down-line connected in the same manner. He tried experimentally: (1) to maintain five lights on the up-circuit, using the up-line as return wire; (2) to maintain five lights on the down-circuit, using the down-line as a return conductor, and successful. Subsequently he carried out the lighting of the station with one main wire only to each circuit, and the rail as the return wire to each circuit. In the third place, Mr. Berly tried to maintain five lights on the up-platform circuit, using the up-line as return at Charing Cross, and the down-line as return at Victoria; and in the fourth place to maintain five lights on the down-platform circuit, using in a similar way the down and up lines as return. Both succeeded separately. He then lighted the station with both circuits connected as in the first, and in the third and fourth experiments, which was done successfully. Later on, namely, on the 2nd and 4th inst., he joined, experimentally, the two wires of Victoria Station into one, making, therefore, a total circuit of about seven miles of wire. He maintained, in the middle of that distance, lights 3½ miles from the Gramme machine, five lights burning, and by the side of which he kept burning another five lights mounted on a circuit of about 250 yards of wire. He reports that both circuits worked admirably with the same brilliancy, and the candles on the short circuit burned very little quicker than those on the long one."

With regard to the progress of the Jablochkoff lights on the Continent, we understand that the Paris Municipal Council has renewed for one year its lighting on March, 1881) the contract for lighting the Avenue de l'Opera, the Place de l'Opera, and the Place du Théâtre Français, with the Société Générale d'Electricité. The Sous Secrétaire d'Etat at the Ministère des Beaux Arts has just given the necessary authorisations to the Société for re-lighting the Salon at Paris in the Industrie in June next. The Hippodrome, which has been lighted for the last two years, and with sixty Jablochkoff lights and twenty Serrin regulators, will be lighted with a battery of 125 Jablochkoff lights, the twenty Serrin regulators being replaced by sixty-eight Jablochkoff lights. The number of the applications of the system has extended to a number of industrial establishments in France and elsewhere since the commencement of the present year, and including the celebrated Creusot Works.

THE DENNARD-ELECTRIC WORKS.—On Friday evening lecture was given by Dr. Siemens on the various applications of the dynamo-electric machine. The commenced with a reference to Faraday's great discovery of the magneto-electric induced current first brought under the notice of members of the Royal Institution in 1831. Prior to that time Faraday had been engaged in testing unsuccessfully if electric currents exist, but with the apparatus then at his command he could not detect them. The utilisation of the induced current was a work of much time and thought on the part of those who followed in the track of the discovery. Stoehrer, in 1841, made the first attempts to utilise it in telegraphy, but the currents were found insufficient to move the recording instrument with certainty. Dr. Werner Siemens, in 1856, arranged a magneto-electric machine with electro-magnets. The first machine on the dynamo-electric principle invented by the lecturer was exhibited by him to the Royal Society in 1867. This machine differed from magneto-electric arrangements in the substitution of electro magnets for permanent steel magnets. The electro magnets were excited by the current produced by the revolution of the machine itself. Electric light is produced by steam, hand or water power, as the power was available by wire at a distance of twenty or thirty miles.

resistance increases in the inverse ratio of the area (or of the square of the diameter) and as the length; but by considering the conducting current and the resistance, these remains are lost to us, while, by considering the resistance, these remains are lost in a mathematical myth. Now, if we take such a drawn-out liquid conductor and put it to the test of experiment, we find that there is not the smallest trace of difference between it and a solid conductor of equal conducting capacity and area; that is to say, the only difference among all classes of conductors is a *difference of specific conductivity*. Liquids have less conducting power than metallic solids, and more than many other solids. But, *given the same conductivity, there is no other difference whatever*. Such a liquid wire may be stretched in a straight line, or it may be coiled up as a helix; it will then have precisely the same powers of producing static induction, precisely the same magnetic actions as a solid wire.

Have we not, then, the right to conclude that in the solid wire there are actions occurring analogous to those occurring in the liquid wire?

We know even that we can extend our liquid wire for thousands of miles, for what is the return earth circuit but such a wire? Mathematicians are, indeed, fond of giving us another explanation, and talking about the earth being an infinite reservoir. But common sense shows that the analogy I have drawn is perfect, and, as a matter of fact, if the two earth plates differ, if one is zinc and the other copper, the intervening earth acts precisely as do the liquids of a common battery, and will set up a current through the wire exactly corresponding to that produced by a common battery.

THREE MONTHS' EXPERIENCE OF ELECTRIC LIGHTING AT BLACKPOOL.*

Electrician April 10 1880

Under this heading I propose to place before you some particulars of the working of the electric light, together with the working expenses of the electric light plant erected last year in our town, feeling sure that it will be of interest not only to yourselves, but to the gas world generally, inasmuch as it is the only town in which electricity has been tried to the best advantage, and on a practical working scale.

In the beginning of May last year our town council unanimously agreed to light up the central portion of their extensive promenade, which has a length of three miles, by means of the electric light, in a manner surpassing anything that had ever been attempted in the way of lighting to be employed every season during the autumn months, and on days of festivity. The opening day was to be the 19th of September, and I may here say that they have accomplished their object of having created a sensational light.

The committee appointed, together with my father, their gas engineer, they proceeded at once to inspect all the best-known systems, viewing, amongst others, the well-known Thames Embankment lights; but so thoroughly satisfied were they that in all these they were lacking but what some large gas lamps would supercede, that they resolved to strike out the rather bold experiment of using the electric light, and employing four naked lights of 6,000 candle-power from the shore. The whole are placed in plain glass lanterns 60 feet above the level of the roadway. This is necessary with naked lights, so as to prevent any strong penetrating power from the eye when approaching the lamps, as well as to better distribute the light between them.

Having thus briefly stated the object desired to be accomplished, I cannot do better than explain the mode of procedure adopted to produce the effect. Arrangements having been come to with Messrs. Siemens, of Charlton, near Woolwich, for the supply of the necessary electric machinery, and with Mr. Bailey and Co., of Lincoln, for the engines, and the whole of the plant being under the control of the Gas Department, it became part of my duty to superintend its erection, and to see to its working after the contractors had completed.

The site selected as being convenient for the machinery was the Corporation Depôt, situated 400 yards from one end of the Promenade, and 250 yards inland. Here was put up a substantial timber building, 50 feet by 25 feet, and inside, on the ground, was laid a framing, which formed the foundations for the machinery, the interspaces between the timbers being filled in flush with concrete, and then boarded over to prevent rising. Upon this were fixed, as they arrived, two portals, 16 horse-power engines and boilers, and at the opposite end were the electric machines, of which there were seven, all being driven from a counter-shaft placed between them and the engines. From each of the six machines a distinct wire is led to its own lamp, and one common return wire, so to speak, answers for the whole. You will, no doubt, wonder what the odd machine was for. Well, at first, the whole of the six machines had to perform the duty of producing their own electricity, but that duty is now taken from them by specially devoting a dynamo-electric machine to that purpose solely, and this was found to be better for the lights.

The first difficulty we had to contend with was the laying of the wires inside the 2-in. and 3-in. cast-iron pipes, it having been decided to place them underground, hidden from view. This proved no easy matter, inasmuch as the wire was in 500-yard lengths, and it was desirable to have as few joints as possible. It, therefore, cost as much to put the wires through as it did to make the trenches, so careful had we to be in order not to damage the insulation, and to keep off the water. The weather happened unfortunately to be unfavourable for us, as, a day or two after commencing, a series of high winds set in, with their usual effect at Blackpool of forcing the water over the Promenade, to the amusement of visitors, but to the detriment of our work; for, at every tide, it filled the trenches and pipes with sea water. However, as there was no time to stop, we proceeded, and completed the 1,500 yards in the week allowed us, and were ready for the preliminary trial to take place on Saturday, the 18th; but, alas! all our efforts were unavailing, for the insulation of the wires had yielded to the water, and it was quite spoiled for the purpose, so there remained no alternative but to withdraw them. This we commenced on the Friday evening, and drew out the whole and laid them on the arms of the lamp-posts. By the Saturday night we had temporarily connected the wires, and had two of the most commanding lights at work with good effect. By the following Monday morning we had collected together the most suitable poles in the town, and immediately set to work and placed them up telegraph fashion, and secured the wires therein with iron staples, there being no time to get insulators fixed. During the time the wires were being completed, experiments and trials were going on in the engine-room, and by Thursday, September 18, all was finally ready, and the lights were lit at dusk with remarkable steadiness, considering the drawbacks we had to encounter for want of time.

I may tell you that it was with no small degree of pleasure I beheld, from an elevated position, the lights shedding down their bright white beams on the crowded forms of at least 20,000 persons who had come to Blackpool to witness the grand spectacle—to see the poor gas once for all annihilated. Well, I must say the gas cut a sorry figure when burning in the lamps when the electric lights were lit, of which a good many of you present were eye-witnesses. The gas was very much reduced in brilliancy darker, and one of the new illuminants was suddenly extinguished, for it would have been unsafe to the public to have left all in darkness, which might have occurred at any moment. As we got more accustomed to the mechanism and freaks of each lamp, not every now and then, we gained confidence because we found out how to apply the remedy. In nine cases out of ten the cause was the rack holding the carbons getting fast, and a man was usually on the look-out to shake it with the line to the lamp. So frequently did this happen that ultimately the passing public and police served us the friendly turn by merely pulling the line as they went by. Sometimes, however, more serious mishaps would occur, owing to the crossed position of the lights, and to the strong gales of wind and rain. The defective working parts were affected by corrosion and damp, and in such cases there was no alternative but to take the lamp in for readjustment; so it had to remain extinguished for the night, or if it was a very bad light, it was better policy to shut it off. One would naturally say, why not take out the spare lamp and substitute it for the other? This seems very well until explained. The reason is this, that owing to all the circuits being of different lengths, and having different resistances, each lamp had to be accurately adjusted, and tried in the test-room, with the current flowing all through the wire. Thus, supposing No. 1 lamp went out, and could not be got to work again; it is 1,400 yards away, and it would be necessary to send two men to lower it, couple the two wires together, bring the lamp back, and act to work adjusting the spare lamp to the circuit, which would require, say, half an hour; then to send it back and hoist it up, the whole occupying 1½ hour, during which the light would be out, and would need another attendant, who would afterwards have nothing to do, and some of nights would never be wanted, although he must be always at hand.

The mode of working which we have found to be the most

* A Paper read by Mr. W. Chew before the Manchester Institution of Gas Engineers.

iron case similar to a postal pillar-box. The erection of these fire alarm boxes at the corners of the streets excites the usual public curiosity, and it is to be hoped that when the systems are set in working order they will prove as valuable as they ought. It is by no means a creditable fact that the Metropolis should have been left for so long a period without such an essential adjunct to the Fire Brigade force; this disgrace seems now likely to be wiped out, and as soon as full scope is given to the system we may hope to see a very considerable diminution in the large and disastrous fires, both to life and property, which are now of such frequent occurrence.

Use of Electric Lighting.

By Dr. JOHN HOPKINSON, F.R.S., of London.

Experiments (Second Paper.)

Read before the Institution of Mechanical Engineers.

Dynamo-electric Machines.—Since the date of the author's former paper in April, 1879, other observers have published the results of experiments similar to those described by him. These results reduced to a curve, in which the abscissæ represent a current passing through the dynamo-electric machine, and the corresponding ordinates represent the electromotive force of the machine for a certain speed of revolution, when that current is passing through it, show the following results:—It will be found (1) that with varying speed the ordinate, or electromotive force, corresponding to any abscissa or current, is proportional to the speed; (2) that the electromotive force does not increase indefinitely with increasing current, but that the curve approaches an asymptote; (3) that the earlier part of the curve is, roughly speaking, a straight line, until the current attains a certain value, and that at that point the electromotive force has reached about two-thirds of its maximum value. When the current is such that the electromotive force is one-half, about two-thirds of its maximum, a very small change in the resistance with speed of engine constant, or in the speed of the engine with resistance constant, causes a great change in the current. For this reason such a current, which is the same for all speeds of revolution, since the curves for different speeds differ only in the scale of ordinates, may be called the "critical current" of the machine.

In Germany, Auerbach and Meyer (Wiedemann's Annalen, Nov. 1879) have experimented fully on a Gramme machine at various speeds, and with various external resistances. The resistance of the machine was 0·97 ohms. Their results are summarised in a table at the end of their paper, which gives the current passing, with resistances in circuit from 1·75 to 200 Siemens units, and at speeds from 30 to 800 revolutions per minute. This relation between electromotive force and current, as deduced from some of their observations, showed that at a speed

which the intensity of the image formed by the lens is compared with a standard light, by means of an ordinary Bunsen's photometer sliding on a graduated bar.

Mr. Dallmeyer kindly had the lens made for the author; he can therefore rely upon the accuracy of its curvature and thickness; it is plano-convex, the convex side being towards the source of light. The curvature is exactly 1 in. radius and the thickness is 0·04 in.; it is made of Chance's hard crown glass, of which the refractive index for the D line in the spectrum is 1·517. The focal length f is therefore 1·933 inch.

Let v denote the distance of the source of light from the curved surface of the lens, and v the distance of the image of the source from the posterior focal plane. Neglecting for the moment loss by reflection at the surface of the glass, the intensity of the source is reduced by the factor $\left(\frac{v}{v'}\right)^2$. But $\frac{1}{v}+\frac{1}{v'}=\frac{1}{f}$, or $v=\frac{fv'}{v'-f}$; hence the factor of reduction is $\left(\frac{f}{v'-f}\right)^2$. The effect of absorption in so small a thickness of very pure glass may be neglected; but the reflection at the surfaces will cause a loss of 8·3 per cent., which must be allowed for. This percentage is calculated from Fresnel's formulæ, which are certainly accurate for glasses of moderate refrangibility, and for moderate angles of incidence.

Suppose, for example, it is required to measure a light of 8,000 candles; if it be placed at a distance of 40 in. it will be reduced in the ratio 40² to 1, and becomes a conveniently measurable quantity. By transmitting through coloured glasses both the light from an electric lamp and that from the standard, a rough comparison may be made of the red or green in the electric light with the red or green in the standard.

A dispersive photometer, in which a lens is used in a somewhat similar manner, is described in Sylvanus's "Lighthouse Illumination;" but in that case the lens is not used in combination with a Bunsen's photometer, nor with any standard light. Messrs. Ayrton and Perry described a dispersive photometer with a concave lens, at the meeting of the Physical Society, on 13th December, 1879 (Proc. of the Physical Society, vol. iii., p. 184). The concave lens possesses however an obvious advantage in having a real focus, at which a diaphragm to cut off stray light may be placed.

Efficiency of the Electric Arc.—To define the electrical condition of an electric arc, two quantities must be stated—the current passing, and the difference of electric potential at the ends of the two carbons. Instead of either one of these, we may, if we please, state the ratio $\frac{\text{difference of potential}}{\text{current}}$, and call it the resistance of the arc, that is to say the resistance which would replace the arc without changing the current. But such a use of the term electric resistance is unscientific; for Ohm's law, on which the definition of electric resistance rests, is quite untrue of the electric arc; and on the other hand, for a given material of the electrodes, a given distance between them, and a given atmospheric pressure, the difference of potential on the two sides of the arc is approximately constant. The product of the difference of potential and the current is of course equal to the work developed in the arc; and this, divided by the work expended in driving the machine, may be considered as the efficiency of the whole combination. It is a very easy matter to measure these quantities. The difference of potential on the two sides of the arc may be measured by the method given by the author in his previous paper, by an electrometer, or in other ways. The current may be measured by an Ohm's galvanometer, by a suitable electrodynamometer, or best of all, in the author's opinion, by passing the whole current, or in his way to think, through a very small known resistance, which may be regarded as a shunt for a galvanometer of very high resistance, or to the circuit of which a very high resistance has been added.

It appears that with the ordinary carbons and at ordinary atmospheric pressure no arc can exist with a less difference of potential than about 20 volts; and that in ordinary work, with an arc about ½ in. long, the difference of potential is from 30 to 50 volts.

The success of burning more than one regulating lamp in series depends on the use in the regulator of an electro-magnet, excited by a high resistance wire connecting the two opposed carbons. The force of this magnet will depend upon the difference of potential in the arc, instead of depending, as in the ordinary lamp, upon the current passing. Such a shunt magnet has been employed in a variety of ways. The author has arranged it as an attachment to an ordinary regulator: the shunt-magnet actuates a lever, which short-circuits the magnet of the lamp when the carbons are too far parted, and so causes them to close.

In conclusion the author ventures to remind engineers of the following rule for determining the efficiency of any system of electric lighting: in which the electric arc is used, the arc being neither exceptionally long nor exceptionally short. Measure the difference of potential of the arc, and also the current passing through it, in volts and webers respectively; then the product of those quantities, divided by 746, is the horse-power developed in that arc. It is then known that the difference between the horse-power developed in the arc and the horse-power expended to drive the machine must be absolutely wasted, and has been expended in heating either the iron of the machine or the copper conducting wires.

78 Manufacturing Engineering

Comparative Economy of Gas and Electric Lighting.

Our contemporary, the *Scientific American*, has taken the pains to institute a comparison, based on practical premises, of the cost of gas with electric lighting from the experience gained in one of the largest Eastern factories, (the Riverside Worsted Mills, Providence, R. I.), where the Brush electric lights have been in regular use for almost a year. The result of this comparison, our contemporary thinks, is the demonstration of the fact that in spacious apartments, where large numbers of gas lights are required, the electric method of lighting may now be adopted with considerable economy. This inference holds good if the facts are correctly reported, both with the Brush and the Edison systems, as compared with gas lighting. The facts alleged in the case presented are as follows:

In one portion of the mills aforesaid, 1,000 gas lights were formerly used, each of about 12-candle power, yielding therefrom an aggregate of about 12,000 candle light, at a cost of (at 2s.6d per 1,000 feet) $12.25 per hour, or $^{1}/_{1000}$ of a cent per candle per hour. In place of these 1,000 gas lights, 50 electric lights of the Brush (1) system were introduced, as above noted; each of 2,000 candle power, yielding in the aggregate 100,000 candles, at a cost of 80 cents per hour, or $^{1}/_{125}$ of a cent per candle per hour. This comparison, presuming that the above statement of cost and amount of light yielded are correct, would show that gas lighting at 1,000 candle candle was over one hundred and sixty times more costly than electric lighting, estimated on the basis of an equal quantity of light by both methods.

Our contemporary then proceeds to show how Mr. Edison's system of electric lighting will figure in the above comparison, taking as the basis of comparison Mr. Edison's own statements as to cost and efficiency. Mr. Edison, it will be well to notice here, proposes to furnish small electric lamps, each having about the intensity of an ordinary gas light of 16 candles, burning 3 cubic feet of gas per hour. He affirms that he gets 10 lamps, or 160 candle light, per hour per horse-power of engine, and that each of his electrical machines furnishes 720 candle light per hour with the expenditure of 5 horse-power.

Applying Mr. Edison's statements as to the cost of the Riverside Mills above, we would have the following showing: Number of Edison lamps required=1,000; number of Edison machines required=52; engine power required=190 H. P.; approximate cost of plant =$16,000; approximate cost of running the same, yielding 10,000 candle light per hour (implying a fixed interest on plant), $1.56 per hour=$^{1}/_{1000}$ of a cent per candle per hour. This estimate of expense, it will be observed, does not allow for the item of royalty to the owners of the patent. It shows, however, that the approximate cost of gas light at the Riverside Mills is light for light, 74 times greater than Edison's system; and that Edison in turn is 10 times more costly than the same amount of light by the Brush system. The relative cost of the several plans is shown below:

Kind of Light.	Cost per Candle Light per hour.
Gas light.....	$^{1}/_{1000}$ of a cent.

THE JABLOCHKOFF ELECTRIC LIGHT.

THE Metropolitan Board of Works has recently had under consideration the question of the desirability of continuing the electric lighting on the Victoria Embankment and Waterloo Bridge, by means of the Jablochkoff system, the existing contract for which will expire on the 10th of April next. The result was that the Board has renewed the contract with the Société Générale d'Electricité for another year on modified terms, and the new contract will expire on the 31st of April, 1880. The Jablochkoff system has now been in successful operation for more than fifteen months on the Thames Embankment, and in view of the further the tension of the contract it was interesting if we gather up the history of its application on to the Illuminations of this public thoroughfare. Our readers will doubtless remember that in October, 1878, the Metropolitan Board of Works contracted with the Société Générale for the lighting by means of twenty lights between Westminster and Waterloo Bridges. The inauguration of the lighting of that section took place on the evening of the 13th December, 1878. On the 10th May, 1879, the lighting of the Embankment was extended from Waterloo to Blackfriars Bridge, twenty lights being added to the twenty already burning. A further extension took place on the 10th October, 1879, ten lights being placed on Waterloo Bridge, thus bringing the total number of lights to fifty. Since these various dates—that is to say, for fifteen months for the first series of twenty lights; 10½ months for the second series of twenty; and 5½ months for the last series of ten—the whole of the lamps have been uninterruptedly kept lighted every night, from dusk until four, or six hours, which is the contract time for keeping the lights burning. These facts are worthy of consideration when it is borne in mind that they were originally laid down for twenty lights only. The extension of the electric lighting not having been contemplated at the time of the plant being laid down, no provision was made for such extension. This necessitated the manipulating and altering of the plant each time the last series of lights was done under the circumstances. It is also to be remembered that another ten lights—those at the Victoria Station of the Metropolitan District Railway—were subsequently added to the fifty already burning, thus making sixty altogether. The price paid by the Metropolitan Board of Works was originally 6d. per light per hour. That price was reduced to 5d. per light per hour on the Board increasing the number of lights to forty; then to 3d. on the number of lights being further increased to sixty, and on the contract being renewed for six months. The new contract is to be carried out at 2½d. per light per hour, the duration of the contract having been extended to one year. The Société Générale contemplates extending the number of lights to certain private concerns from the centre at Chiswick Cross.

The Jablochkoff system of electric lighting is now in use under almost every possible condition and in every variety of establishment. It is used in streets, on bridges, in railway stations, theatres, circuses, engineering and every variety of industrial works, docks, basins, on board steam-vessels, in hotels and private residences. Crowned and uncrowned heads have also adopted it. King Theebaw, of Burmah, has had sixty lights fitted up in his palace at Mandalay; Shah Nasser ed Deen, of Persia, four in his palace at Teheran; Prince Agrakhan, six in his palace at Bombay; King Don Luis I., of Portugal, six in his royal palace of Cintra, and the Queen Isabella of Spain, six in the conservatory of her beautiful residence in Paris. At the present time there are 565 lights on the Jablochkoff system burning in Paris, 418 in the French provinces and 813 in foreign countries, making a total of 1716 lights, 198 of which are in use in this country. This all denotes progress, and as regards its application in London the Metropolitan Board of Works is to be commended for the spirited way in which they are practically testing the question of electric lighting.

DYNAMO ELECTRIC MACHINES.

Messrs. [illegible] firm of telegraph engineers, late, says *Engineering*, recently published a series of very important researches on the theory of the Gramme machine and other forms of dynamo-electric and magneto-electric generators, in the course of which the services at some extremely interesting results, and clears up a number of points which hitherto have been comparatively obscure in the operation of such machines. Starting from first principles and the simplest experimental data, M. Breguet propounds the successive steps of a logical chain of reasoning to link the grand discovery by Faraday of magneto-electric induction with the applications of the principle in the machines of Gramme and Siemens. He is thus enabled to explain a point hitherto supposed irreconcilable with theory, namely, the retention of electrical energy in setting the "brushes" or collectors of the current in the dynamo-electric machines in an oblique position against the commutator, and unsymmetrical with respect to the field magnets of the instruments. He not only explains this, but points out that it is an absolute necessity of the case, and that upon this position with regard to whether the machine is better suited to be a generator or an electro-motor. He further explains, for the first time, the rôle played by the ring of iron in the armature of the Gramme machine. And lastly, he thus indicates the action of the Siemens machine, and shows that there is at least one method of winding the wires upon its armature superior to that adopted hitherto in practice. It is proposed to treat in the present article of the earlier and more general portions of M. Breguet's research, reserving an account of his work on the Gramme machine and on the Siemens machine for subsequent occasions.

The first principle laid down by M. Breguet is the essential proposition of the Gramme and all other dynamo and magneto-electric machines. Resisted by mechanical means, they supply a current of electricity derived from the energy of a steam engine or other motor. But if you supply them with a current of electricity they will, conversely, rotate and turn the electricity back into mechanical energy. The same thing is true of all electro-magnetic engines or electro-motors, such as those of Hjelmlie, Page, and Froment. They are intended to rotate by electricity, but if you rotate them by mechanical means they will furnish in turn a current of electricity. This principle of reversibility extends even to some unexpected cases. Very early on in the history of magnetism Barlow found he could cause a wheel or disk of copper to rotate between the poles of a magnet by sending a current at the same time perpendicularly through it. He fixed from the axis to the circumference, where it passed into a pool of mercury, a copper wire. The mercury contact with as little friction as possible (Fig. 1). In 1831 Faraday per-

Fig. 1.

formed the converse experiment, and found that by mechanically rotating a copper disk between the poles of a magnet he thereby generated a current in a wire the two ends of which touched the circumference and the axis of the wheel, which were amalgamated over with mercury, so as to insure better contact with the wire (Fig. 2). Here, then, is the

---

13

Fig. 2.

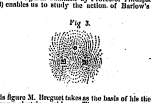
simplest kind of electro-motor and dynamo-electric generator, and it illustrates at the outset the important principle of *reversibility*.

The second matter which claims notice is the mutual interaction of a magnet and a conductor which carries a current. We sometimes speak loosely of the displacement of a current caused by a magnet when we mean that the conductor carrying the current is displaced. Although the term is convenient, it is scarcely accurate, for we must distinguish between mechanical force, or that which tends to move matter, and electro-motive force (as above), which tends only to move electricity in a conductor. This mechanical reaction between magnets and current conductors which turn machines are electrically of the former class. These reactions, therefore, deserve to be studied from a nearer point of view by applying a principle announced by Faraday in startling magnetic attractions, and lately further extended by Professor S. Thompson to the case of the attraction between currents. Faraday first recognized the significance of the so-called lines of magnetic force which are seen crossing in curves through every magnetic field when iron filings are sprinkled over it. Without necessarily attributing to these lines any physical existence, we may conveniently employ them as Faraday did, to investigate and to describe the actions between magnets or magnetic bodies. Faraday laid down the following properties as those possessed by these lines of force: First, the lines of force tend to shorten themselves. Secondly, lines of force lying in the same direction side by side repel one another. To these M. Breguet adds that a line of force, when it passes through iron or other metal capable of magnetic susceptibility, must be regarded as if shorter than one of equal actual length passing through air, so that the "tendency to shorten" may exhibit itself by a tendency to run through a magnetic substance near at hand.

The means of these simple principles Faraday was able to deduce the laws of magnetic attraction and repulsion from the figures formed by the lines of iron filings when sprinkled over the magnetic field whose properties were thus to be investigated. Professor Thompson has applied the same reasoning to the case of the attractions and repulsions exerted between two currents assumed to circulate, and a magnet.

One of the figures introduced by Professor Thompson (see, Fig. 3) enables us to study the action of Barlow's wheel,

Fig. 3.



and this figure M. Breguet takes as the basis of his theory of the dynamo-electric machine. The two magnets are shown as the poles of the magnet, and a point a little way from them is taken as the centre of the conductor perpendicular to the plane of the figure, and the current in a current which passes downward through the paper. Now the current produces a magnetic "field" all round it which, if the magnet were not present, would consist of lines of force forming concentric circular circles. But in presence of the magnet and its system of lines of force there is a mutual reaction, the nature of which can be learned by simply looking at the figure formed by the iron filings. The tendency of the lines to shorten would assuredly urge the conductor toward the poles of the magnet; and in Barlow's wheel, where this goes on continually in the part of the disk lying between the poles and the mercury cup, the simple attraction becomes a movement of rotation.

A current passing in the opposite direction through the wire would obviously be urged in the contrary direction or away from the magnet. Conversely, if the conductor were removed from the magnet further away from the magnet a current circulating in a contrary direction to that which would be generated of opposite direction to that which caused the motion, the electromotive force of the current being proportional to the number of lines cut by the conductor in a second of time.

Following M. Breguet, we next pass to a consideration of the first and simplest of electro-motors, as shown in Fig. 4.

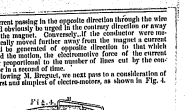


Fig. 4.

This apparatus consists of a metallic conductor bent twice at right angles and balanced on a center at a point X. The vertical branches carry little metallic pointed segments which dip into the halves of a circular mercury cup divided across by a diametrical partition into two portions connected respectively with the poles of a battery; and the whole is placed between the poles P N of a magnet, so placed that the line joining the two poles is at right angles to the diametral line. The conductor rotates upon its center so long as the current passes. We may consider separately the action of the magnet on the two vertical portions, I, I', and on the horizontal portion, H. The action upon the two vertical portions of the conductor is best studied by taking a plan of the apparatus, as shown in Fig. 5, which gives in diagram-

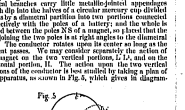

Fig. 5.

matic outline all the working parts. The arrow indicates the direction of the current, which therefore ascends at I, and descends at I'. Connection between the contacts which here exist and those which gave the magnetic figure, Fig. 3, with iron filings, will show a section of lines of force, of which the most characteristic will be the S-shaped curve shown by the dotted lines. Hence the tendency will be to displace I toward the top of the figure and I' toward the bottom, and their positions of equilibrium will be respectively C and C. But if the inertia of movement carry the conductor across past these points and make them touch the opposite mercury cups, the current will be reversed, I being drawn toward C and I' toward C. Hence there will be a continuous rotation, the direction of the current in the conductor being reversed at every half revolution when the moving wire passes through the position of equilibrium at C C'. A little consideration will also show that the action upon the horizontal portion, H, is similar, and adds itself to the forces producing rotation.

Now suppose that, instead of the simple wire bent twice at right angles, a conductor be taken having the vertical branches prolonged into two arcs, and carrying, as in Fig. 6, four little pointed contact pieces. We shall now require

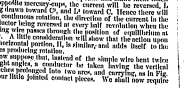

Fig. 6.

the mercurial cups to extend over 90° of arc, *i*, *i*, extending from C only as far as B, and from C only as far as N. Had we taken eight little contact pieces, each mercury cup need only have occupied one-fifth of the circle, or 45° of arc. If the number were indefinitely increased, then the arcs subtended by the mercurial cups might be diminished down to mere points at C C. These considerations hold equally good in the converse case where the instrument is used as a generator of currents.

One further step remains to be considered before we pass on to the application of these motions to the Gramme machine. Instead of the simple wire we may take a wire coiled upon a frame, as in Fig. 7, and having many turns. On each wire of this coil there will be a similar action; hence the total force of rotation will be proportionately greater when an equal current is used. In all the various arrangements hereafter to be described, every single wire may be considered in a similar way to represent a coil, and hence the figures may be made as simple as possible. It will be noticed that the single flat coil of Fig. 7, if wound upon an

Fig. 7.

iron spindle and frame, virtually constitutes an armature of the type introduced by Siemens, and applied by him in the early magneto-electric machines, and also recently employed by M. Marcel Deprez in the excellent little electro-motors which he has constructed.

M. Breguet's application of these ideas to the Gramme machine and to the Siemens machines of modern type will be dealt with in a subsequent article.

The object of this machine is to obtain by improved arrangements and construction of parts a greater intensity of the magnetic field of the revolving armature, and so to generate a greater amount of electricity than can be produced with machines of other forms, and also to provide means for the governing of the current and cooling the magnets.

The construction of the apparatus is shown by figs. 1, 2, 3, 4, and 5, and it is as follows:—As are end standards, A, having bearing, circular surfaces, and serving as stationary discs, these are bolted to a bed plate, B; the standards having central bosses through which passes the central main driving shaft, C. On the inner surface of these bosses, the stationary magnets, D, are radially arranged in a manner to be more fully described later on. The shaft, C, carries a pulley on one end, to which is connected the driving machinery, the other end of the shaft carries the commutator, E, the extremities of the shaft being supported by bearing standards, F, fixed to the bed plate, B. On the main shaft, C, between the standards, A, is mounted a disc, F, upon both sides of which are bolted radial magnets, a number and size required according to the area of the disc; the disc when so fitted constitutes a revolving armature. The magnets of the stationary discs and the revolving armature are constructed as follows:—Two soft iron plates, *d*, *d*, of approximately sector form, are connected by a solid or hollow connecting piece, *c*, of steel or iron of corresponding shape to, but smaller than, the plates; one of the plates, *a*, serves as a flange for bolting the magnets, G and D, respectively, either to the revolving disc, F, or to the stationary disc, A, and the other plate, *b*, acts as the soft iron keeper of the magnet. The connecting piece, *c*, of the plates of the magnets is hollow or solid, and serves as the core upon which the wire is wound. In small machines, the connecting piece or core may be solid; the connecting piece of the stationary magnets, D, is, in all cases, longer than that of the revolving disc magnets, G, so as to receive a longer coil of wire; in fig. 1 the core of the magnet, D, are shown hollow. The magnets are bolted in a circle on to and around the revolving and stationary discs, F and A, respectively, and are relatively opposite to each other, so that the revolving disc will carry and be furnished with a circle of magnets upon each face, so as to revolve in face of corresponding sets of magnets on the stationary discs, A, of the standards.

The centre of the revolving disc is fitted with a bush, H, in which are holes lined with insulating material, through this bush are passed the wires of the coils of the magnets, G; these wires are carried along the shaft to the commutator, E, thence through a perforated bushing, H, fixed on the shaft, C, which works in the boss of the standard, A. The wires are insulated by passing them through small tubes of insulating material, as will be understood by reference to figs. 3 and 5.

The wire upon the opposite stationary magnets is wound and connected in such manner as to give opposite polarity to each magnet facing the other, and so forming pairs between which the armature revolves.

For machines of large construction, and where larger currents are to be developed, the number of the armatures, F, and the stationary magnet

standards, A, may be increased; thus, for a machine having two of the revolving armatures upon the shaft, C, there will be provided three stationary magnet standards, A, and so on.

To keep the hollow magnets cool, the stationary disc is perforated at the back of its magnets, and a blast or current of air from a fan can be directed by tubes, T, into the hollows of the magnets, outlets being also provided for circulation of the air through them.

The governor, which cuts the circuit when the machine ceases working, is shown in figs. 1 and 4.

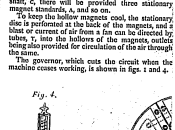

Fig. 4.

In this arrangement, contact will only be made by the saddle-shaped plunger upon the machine attaining the required speed, and so depressing and immersing the extremities of plunger arms one into each cup of mercury. The mercury is covered with glycerine, and ends of the plunger arms which dip into the mercury are platinised to prevent oxidation and to ensure perfect contact. A flexible cover of thin rubber cloth, secured by a ring, keeps out dust and dirt from the cups. In Westcott's machine, even when the speed is very low, the mercury is thrown up in a spiral column, thereby making con-

TELEGRAPHIC APPARATUS IN USE IN THE BRITISH POSTAL TELEGRAPH DEPARTMENT.

RELAYS *(continued)*.

A GENERAL view of the *Standard* Relay is shown by fig. 30, the cover being removed and placed by the side of the instrument.

Slowest Relay.

This form of relay is used to a greater extent than any other kind, and its general construction is very generally known. A top view of the instrument is shown by fig. 31. It consists of an ordinary electro-magnet, the poles of which are provided with soft iron shoes, or pole pieces, A, A'. A

THE MAGNETISATION OF INDUCTORS BY ALTERNATING CURRENTS. SUPPRESSION OF THE MACHINE FOR EXCITING DYNAMO-ELECTRIC MACHINES GIVING ALTERNATING CURRENTS.

By M. DE NERIENS.

Read January 1886

Are magneto-electric machines preferable to dynamo-electric machines for the regular and economical production of light? This question, which was long ago purposed, has not yet received a solution. It is in fact very difficult to give a satisfactory answer to it. Each of these types of machine has its factory advantages and its drawbacks. The magneto-electric machine has on its side the inevitable magnetism of its inductors. If it has on its side the inevitable magnetism of its inductors. If it has on its side the inevitable magnetism of its inductors. If it

The Wizard Defends the Electric Light, and Says, "Yes Just Wait."

Edison Coming West to Investigate Ore Reduction.

A New Water-Proof Invention—Cloths, Cards and Leather Preserved.

Vanderbilt—Mimic Fitch—The Whale.

(Special Correspondence of The Tribune.)

New York, April 16.—I went out to Menlo park on Wednesday to see what progress Edison was making with the electric light and the ore milling process, and to see if he had any new schemes to let loose.

I was surprised to find him looking so well. He was dispirited in a new suit of blue flannel and about twenty pounds of extra flesh, which he has added himself to since I saw him last fall. "Yes," he said, in response to congratulations, "I am getting fat. I weigh 190 at least; I grease more. Sleep from 11 to 7 every night, eat three sizeable meals a day—that's the secret of it."

"Why," said I, "you're grown young ten years this winter."

"I have escaped from the hard work and worriment that the electric light imposed," he said. "Since I finished that I have nothing to worry me."

The visitors looked at one another inquiringly, till one got the courage to say: "But your lights, Mr. Edison, are not up in New York yet, and even the fifty that were glowing here night and day for months here been put out. How is that?"

"There is a vile difference between compiling an invention," said he, "and putting the manufactured article on the market. The public, especially the public of Journalism, stubbornly refuses to recognize this difference. I have solved all the problems I was engaged on in the matter of the electric light, and have finished it. I can light a city at one-fourth to one half the price of gas; I have proved it time and time. I have put out my lights because there is no longer any need of them. The lamps, conductors and generators are now being made for the demonstration on a larger scale, first here, then in New York. But this involves all the details of manufacturing, and it take time."

"The public inquisitiveness probably ceased," I said, "by the great saturations of the gas companies."

"Yes, but it is always so," he said. "It was years after photography was invented before the first photograph was taken; years after the steamboat and telegraph were invented before they were actually set going, and it was ten years after Stephenson made his first locomotive before he set the 'Rocket' on the track between Liverpool and Manchester. He and Fulton got even more cool to being called 'fool' and 'failure' and 'fraud' than I have. So I don't mind it much."

—Engineering.

The Progress of the Electric Light.

Cork trade journal 27 1882

The electric light being now fairly launched upon its practical career, it is both useful and instructive not only to observe the steps in the general public, to have the latest novelties exhibited and the whole question intelligently discussed in such a manner was done during the two last meetings of the Society of Telegraph Engineers. The occasion of a paper by Mr. Alexander Siemens, a nephew of Dr. C. W. Siemens, F. R. S., was seized by the President, Mr. C. F. Varley, F. R. S., to bring together those inventors who had novel lamps to show, and the result was a very interesting meeting which completely filled the hall of the Institution of Civil Engineers, and testified by the number of strangers present that the electric light is a name to conjure by, and that public interest in its success does not seem to have abated.

After tracing the principal causes which led to the recent revival of electric lighting—the illumination of Paris boulevards during the Exhibition year and the Edisonian "scare"—Mr. Siemens dealt with the merits and demerits of electric light apparatus, under the two heads of dynamo-electric machines and lamps; but in illustrating his remarks in very properly confined himself to the apparatus with which he is best acquainted, and for which it is natural that he should have a prepossession, namely, that of the eminent firm with which he is connected, Messrs. Siemens Brothers.

It must be considered as beyond a doubt that, for producing powerful centres of light, electricity is already far superior to gas, both in point of economy and beauty; and every improvement in the apparatus for producing the electric light only renders the superiority more apparent. Dr. Hopkinson has shown that a dynamo-electric machine yields in electricity some 90 per cent. of the mechanical power expended on it, and therefore we cannot expect much improvement in this direction. In the old system of dynamos the current from the rotating armature was passed through the coils of the field magnets and the lamps one after the other in circuit; but in late machines Wheatstone's plan of splitting up the current after it has traversed one part round the magnets, and the rest through the lamps, was adopted, because by its means the strength of the inducing magnets was less subject to variations with variations in the resistance of the external circuit. A still better method, however, is to have a separate machine to excite the magnets to a constant strength, such as is employed by Dr. Siemens in lighting the British Museum. Another point to be attended to is the proportion between the resistance of the voltaic arc and the rest of the lamp circuit. If, for instance, the arc gives 1 ohm, and the rest of the circuit only 0.1 ohm, then when the carbons touch there will be a reduction of 90 per cent. in the total resistance of the working circuit. It is better, therefore, to make the resistance of the rest of the circuit 1 ohm as well as the arc, so that when the carbons touch, the fall in resistance will only be from 2 ohms to 1 ohm instead of from 1.1 to 0.1.

There is, Mr. Siemens pointed out, far more room for improvement in the lamps than in the machines. A good electric lamp should be a single, and, therefore, convenient and cheap; it should keep lit a long time, and should be steady, without affecting the others in circuit; it should burn steadily, silently, and be capable of easy adjustment. A great number of patents have been taken out for electric lamps recently, but it would have been better for the inventors if they had first taken the trouble to consult Colonel Bolton's summary of English patents on gingerees, for many of these old contrivances over again are really old.

Incandescent carbon wicks, first patented by De Moleyns in 1841, and recently worked out by Regnier and by Werdermann, are subject to the defect of consuming rapidly in oxygen of the air, and as they give out a feebler light than the arc, they are consequently more costly than the arc, but on the other hand their steadiness is matchless, and owing to the very feebleness of their light they are best suited for domestic illumination. Perhaps the best incandescent lamp hitherto invented is that of Lane-Fox, which is especially designed for lighting mansions, picture-galleries, ships, and theatres, does not expose the curtain to the air so that it is liable to burn rapidly away; neither does it in close it in a vacuum or a vessel filled with nitrogen gas after the method of Edison and of Messrs. Sawyer and Mann. The incandescent carbon is simply enclosed in an air-tight vessel, and allowed to burn all the oxygen present into carbonic oxide. The inventor of an hour, and the waste of a small piece of carbon, suffice for this process, and when it is completed the carbon pencil burns only at the rate of 1 in. per hour, and a 20-cp. light is found in practice to last 100 hours. There is only one carbon pencil of small diameter employed, and it stands upright and is pressed down in a groove cut across a copper block which forms the negative electrode, to the incandescent point slowly consumes away, the carbon rod, sinking shorter and shorter, sinks within the vertical tube protecting it.

It is of great importance to secure a perfectly air-tight vessel so as to prevent air from entering and forming an explosive mixture with the carbonic dioxide, and the best air-tight joint Mr. Andrew has yet obtained is the "water joint" of Mr. Brougham. The water allows the heated carbonic dioxide within the receptacle of the carbon to escape but prevents the external air from entering. This vessel was lighted by 20 of these lamps, each giving a 20-candle light, and all fed by one small Gramme machine of the A type.

Mr. Siemens then turned to electric lamps giving a "voltaic arc," and explained those invented by Von Hefner Alteneck, the chief assistant of Dr. Werner Siemens, and by Dr. C. W. Siemens, but as these have been already described in our pages we need not dwell upon them here. The one forms, however, decerve mention. The first is the pendulum lamp, regulated by the current passing through a solenoid, which attracts a movable core and liberates an oscillating frame. The frame bears a vertical rack carrying the positive carbon, and feeds the latter downward's until the arc is re-established, when the frame is lifted by the action of the solenoid. In the other lamp the carbons are placed in a horizontal position one over the other, and the feeding mechanism is set in operation of the current in a solenoid on a moveable core is, by means of two bell-crank levers and two pulleys, made to draw the two carbons together. A reflector placed over the arc collects the rays and throws them by projecting them downwards.

Some valuable figures showing the cost of Siemens' light were then cited by the author. From these it appears that to maintain a 6-cp candle light by Siemens' alternating machine, four horse power are required, and 3 lb. of carbon are consumed per hour. With a gas engine to give the power the relative cost of gas and electricity for 6,000 candles is 4s. 10d., and 2s. 7d., the saving by the use of electricity amounting to 47 per cent. By the use of Siemens' permanent magnet machine, however, a saving of no less than 87 per cent. is claimed. With good steam engines to supply the power these percentages would be still higher. But such powerful lights, it must be remembered, are of limited application, and, therefore, gas shares need not be affected by results of this kind. At the Albert Hall a nightly consumption of 250 000 cubic feet of gas costing £7 7s. 6d., is obviated by the employment of the electric light and a saving of 98 per cent. effected; and at Blackpool six electric lights of 6,000 candle power, and costing £5 5s. 10d., displace for £7 5s. worth of gas, with a saving of 64 per cent. At the British Museum, where the use of Siemens' electric light has doubled the time after dusk permitted to readers, four lights of 1,000 candles each are maintained within the reading room, and seven of 1,000 candles each in the vestibule and outside front. These in the reading room are fed by four continuous current machines, the others by one alternating machine, and a fixed exciting machine is used for all. The lights are all worked up to their full power. In the morning after the fresh carbons are put in they are learned a little to see that all is right, and the engine fires kept up all day, so that the light can be started in a moment after dusk has set in. By this plan the cost is raised a little; but notwithstanding the total cost for 300 hours of lighting is only £100 1s. 1d., or about 6s. per hour, comprising 2s. 9d. for the light, and 3s. 3d. for engine driver and other attendant expenses. The cost of gas would be 16s. per hour, and thus a saving of 60 per cent. is effected.

During the meeting Mr. Crompton exhibited his lamp, and for absolute steadiness and great splendor it made a fine display. A full description was given of it in 'Engineering,' vol. xxviii., page 17, but we may say here that its great success lies in the fact that the movable part of the lamp is regulated by the current in a manner so as it is made as possible. Instead of making the regulating current actuate a heavy armature or movable core, as is often done, Mr. Crompton makes it influence an armature in a soft iron armature, and this again attracts a second three-pronged armature, and this again attracts a second three-pronged armature of very small mass. The attraction of this second armature (which by virtue of its small mass is sensitive to slight variations in the current) is opposed by the first armature) causes it to apply a light friction-brake to a wheel which is the last of a train of wheels driven, as in the Serrin lamp by the weight of the descending upper carbon which it controls, feeding it to the arc in an absolutely uniform manner.

The adjourned discussion on Mr. Siemens' paper was opened on the following Wednesday evening by the reading of the secretary of a very interesting communication from M. Berly, the representative in this country of the Société Générale d'Electricité, who after referring to the early history of the Jablochkoff system of electric lighting, and the steady progress which it has been making since it was first installed in the side room of the Grands Magasins du Louvre two and a half years ago, described the four installations of the system in the Place and Avenue de l'Opera and the Paris Hippodrome in 1878, and stated that the Municipal Council of Paris has just renewed the contract with the company which he represents for continuing the lighting the Place and Avenue de l'Opera, the Place du Theatre Francais, and the facade of the Opera House itself for another year, ending in March, 1881. The progress of the system in London is somewhat interesting; it has been steadily extending on the Thames Embankment, starting from twenty lights in December, 1878, to which were added in May, 1879, a further series of twenty lights, and in October of the same year ten more were added by the lighting of Waterloo Bridge, bringing the number of lights all fed from the one station at Charing Cross to fifty, since which time the system has been set on the Victoria Station of the Metropolitan District Railway, and to the board room of the Metropolitan Board of Works, the current for all the lights being supplied by the machine at Charing Cross driven by the same engine of Messrs. Ransomes, Head & Co.

In addition to this experimental adoption of the Jablochkoff system for public lighting, it has also been introduced at the private establishments of Messrs. Shoolbred & Co., in Tottenham Court-road, Messrs. Crocker & Sons, Mr. Nevil, Messrs. Siemens Brothers, and others. But the most complete installation that has yet been made, was in the Palais de l'Industrie for the fine art exhibition familiar to all as the Paris Salon, which is lighted by no less than 256 Jablochkoff lights and the present moment there are as many as 1,716 Jablochkoff lights in regular use, 196 of which are in this country. Concerning the question of the cost of the system, considerable advances have been made, for whereas the Metropolitan Board of Works originally paid the rate of 6d. per light per hour, it was, as the system became extended, reduced first to 5d., then to 3d., and it is now supplied at the rate of 2½d. per light per hour, and at this price the contract has been given for lighting the Victoria Embankment and Waterloo Bridge for another year to terminate on the 10th of April, 1881. Again the Jablochkoff candles have not hitherto been reduced in price, but their period of burning has been increased. The first candles were supplied at 9d. each, but in a short time the cost was reduced to 7½d., then to 6d., and then to 4d., at which figure their price remains. The new candles are capable of lasting nearly two hours. Besides the reduction in cost, other minor improvements have been made, and a very interesting series of experiments have lately been conducted with a view to ascertaining the precise manner in which the candles are consumed, and the best distance at which light can be satisfactorily maintained from the machine or apparatus, and upon the very important economic question as to the employment of the earth as a return circuit. By coupling up the various circuits running between the Victoria Station and Victoria Docks and working up to their full power. In the morning after the fresh carbons are put in they are learned a little to see that all is right, and the engine fires kept up all day, so that the light can be started in a moment after dusk has set in. By this plan the cost is raised a little; but notwithstanding the total cost for 300 hours of lighting is only £100 1s. 1d., or about 6s. per hour, comprising 2s. 9d. for the light, and 3s. 3d. for engine driver and other attendant expenses. The cost of gas would be 16s. per hour, and thus a saving of 60 per cent. is effected.

Among the other lamps recently perfected, that of Mr. Heinrichs was exhibited last evening, this apparatus has already been described in these columns, and the improvements lately introduced by M. Heinrichsmann into his system were exhibited and explained.

It may be convenient to mention here that the lecture theatre during the evening was exclusively illuminated with Mr. Crompton's lamps, and those behaved in a most admirable manner, although far from the satisfaction of their inventor. We may also refer to an interesting review prepared by Mr. Conrad Cooke, at the request of the President, of the progress made in the question of electric lighting during the past eighteen months, and in the course of which he reminded the meeting that as electrical engineers they must all be interested to a great extent in the zeal and enterprise with which the Societe Generale d'Electricite had during the time of the Paris Exhibition demonstrated the complete applicability of the electric light to street illumination, and by so doing, had first set into motion that great wave of public interest to which so much of the recent extraordinary development of the subject was due. He considered that the improvements in the system in Paris and the very interesting experiments of M. Berly of the greatest importance, for they went to show that what was at first considered a very extravagant system could under proper management be made an economical one, and they demonstrated to conclusion the feasibility of lighting the largest rooms in the country, if not the world, from a central station, say from two or three centres. A radius of 3½ miles represented a circle of nearly 40 square miles, and M. Berly's experiments had shown that the electric light was illuminant at that distance from the generating station. Referring to the Bapieff system which was introduced under very informal patronage, he was somewhat surprised that it had not extended beyond the walls of the Times office, and had considered that some description of the system of this system which rendered it unfects must have been discovered in this system which rendered it unsuitable for general adoption, but he had within the last few days learnt that the light was giving great satisfaction to the authorities of the Times, so much so that it has been greatly extended, and was still further intended to other departments.

Turning next to the Wredentown system, which he considered probably the weakest of all systems of electric lighting, Mr. Cooke attributed the failure, mainly to its occupying an intermediate position between the Jablochkoff and the incandescent lights partaking of the character of both, the carbons, instead of being of two united a sectional area at the point to conduct the whole of the current, became highly incandescent by the passage through it of a portion of the current, the excess emptying as a sort of false leakage or arc which surrounded the incandescent point, and by this duplex nature of the source of light the arc and the incandescent burned, for diminishing intervals of time, and therefore tending to a mutual compensation.

Mr. Cooke referred to the Brush system, which he considered as likely to play a very important part in the future development of the electric light. Mr. Cooke, turning to the question of regulators, said, judging from the performance of the Siemens "pendulum" lamp, it appeared that that regulator worked the best so long between the feeds, and when it did not so to work with sufficient rapidity; he had, however, seen the feed it did not do so that the lamp was frequently extinguished, and the same form of lamp performing with the greatest steadiness, and the discussion was probably due to imperfect adjustment to the current. He considered Mr. Crompton's lamp to have very special claims to having solved the question of regulating the electric arc, for in it the existing solved the question of regulating the electric arc, for in it the existing arc was acted on so slowly or so rapidly as they are commenced, and in practice lamps act slowly or rapidly as they are commenced, and in practice lamps act slowly or rapidly as they are commenced, and in practice lamps are fed by a continuous motion rather than by an alternate feeding and stopping action, which must tend to produce fluctuations in the light.

Mr. Crompton pointed out that the cost of cables would be an expensive item in electric lighting. He had tried the "earth" as a return wire, and found that it was the varying resistance of the earth plates; and, moreover, he had observed that the mass of the wire had something to do with the conduction independently of the resistance.

Mr. Ladd, as representing the Brush system, claimed for it the merit of being the one most perfectly adapted for the illumination of large places, not only on the ground of absolute steadiness, great power, and simplicity, but on the point of economical working; he instited simplicity, but on the point of economical working; he instited that the Brush system in the Liverpool Station, where the system is at members to go to the Liverpool Station, where the system is at work, and judge for themselves, and he felt sure that they would come to the conclusion that for a powerful steady light it could not be excelled. Mr. Crompton, in the course of a number of places where the present, in consideration of the fact that the Brush system has been adopted, all of which installations have given the greatest satisfaction. Mr. J. S. Shoolbred called special attention to the very interesting statistical information contained at the end of Mr. Siemens' paper relative to the question of cost, a question which after all must, to a great extent, determine the success or failure of any system as a practical application.

The President, before proposing a vote of thanks to Mr. Siemens for his paper, spoke upon the general question, and in the course of his remarks called attention to the urgent need of some more scientific standard of photometric measurement than that extremely unsatisfactory so-called unit, a normal candle, which conveyed no sort of idea of what was intended and gave rise to endless confusion, and we most

completely endorse all he said with respect to the extremely unsatisfactory state of the question of photometry which is acknowledged on all sides. But the problem is one which is not by any means simple of solution and has occupied the attention of scientific men for a long time past. With respect to the comparison, however, of electric light systems with other systems of illumination, and with one another, we cannot but think that the suggestion made by Mr. Preece is a valuable one, namely, to estimate a light, or a system of lighting, not by its specific intensity but by the area of ground it is capable of illuminating to a given standard or at a given cost of production. This is the practical question to be solved, and we should be very glad to see it adopted in making comparisons between different illuminants.

THE BRITISH MUSEUM AND THE ELECTRIC LIGHT.—On Saturday morning orders were given to suspend all the lamps in the reading room of the British Museum and the approaches which have been used during the last three months in conveying the electric light and enabling readers to remain in the Museum library up to seven p.m. During the month of April, therefore, the reading room will be closed at six o'clock every evening, to which hour the galleries will also remain open. The electric light has, however, been such an eminent success as an experiment that the Treasury, and reported on Saturday, that matters must remain *in statu quo*, from the simple fact that no money had been voted to cover the extra expense of removal.

---

negative to the other. Mr. Bidwell also showed by a simple experiment that the action of Edison's receiver was electrolytic. He caused the same passage of a current to lessen the friction of a metal strip on a drum covered with moist paper, and thereby thinned the drum by the evolution of hydrogen.

Professor Ayrton pointed out that the rubbing action in these experiments assisted the current by bringing up fresh electrolytic matter, a fact which had been taken advantage of in the construction of several batteries.

Professor Adams remarked that this explanation did not seem to explain how the current was *reversed* in the cell composed of *two* tin-foil plates.

Professor Guthrie then demonstrated by experiment a curious anomaly in frictional electricity. When flannel is rubbed with ebonite the flannel is + electrified, when ebonite is rubbed with glass the ebonite is + electrified, and we should therefore expect that when flannel is rubbed with glass the flannel would be still more + electrified; but instead of that it is really feebly negative. Perhaps this fact that the best of friction entering into one substance more than the other affected such results.

The Secretary then read a note from Mr. Ridout stating that he had succeeded in Dr. Guthrie's funnel experiment mentioned at last meeting, and, by means of a stream of water flowing out of a glass funnel, had attracted a glass cone towards the mouth of the funnel. The angle of the cone was greater than the angle of the funnel.

THE SOCIETY OF TELEGRAPH ENGINEERS.

AT an ordinary general meeting of the Society, held March 24th, Mr. W. H. Preece, President, in the chair, the minutes of the last ordinary general meeting having been read and confirmed, and the list of new and proposed members having been read, the discussion on Mr. Alexander Siemens' paper on "Recent Improvements in Electric Lighting" adjourned from the last meeting, was continued.

At the commencement of the discussion a communication from M. Berly was read by the Secretary.

In 1877-8 Jablochkoff candles were in use at the Magasin du Louvre; this number was since increased to 120, produced by means of a 100 horse-power engine. These had been worked for 2½ years without intermission and with perfect success.

In February, 1878, the Avenues Picquois and other buildings were illuminated by the Jablochkoff system. The Place de Circnl Carrée was also lighted.

In 1878 the Metropolitan Board of Works commenced to light the system on the Thames Embankment, using lights being used; subsequently other lights were added, on Waterloo Bridge and also the Embankment to Blackfriars Bridge. The number of lights now in use is 200. Messrs. Goodhew's establishment, in the Tottenham Court Road, was also lighted by the Jablochkoff system, 25 lights being now in use; several other establishments, Messrs. Nicolls, in Regent Street, and Messrs. Samuel Brothers, Ludgate Hill, amongst these. The Picture Gallery, or Salon, in Paris, has also been lighted by the system, 16 dynamo-batteries of 16 lamps each being employed for the purpose. The total number of candles at present in use is as follows:—56 in Paris, 428 in the provinces, and 823 in foreign countries, or 1,308 in all. In this country there are 198. The cost for a large number of candles was 2d. per hour per candle, but this has now been reduced to 2½d. per hour. The cost of the candles, which was originally 8d. each, is now reduced to 4d., the candles burning two hours each, this would be shortly increased to three hours. As regards cost per horse-power, this had been reduced from 9d. per horse-power per lamp to 3d. per horse-power per lamp. An improvement in the candles was effected by covering them with a coating of electro-type copper. A form of candle which rolls itself if extinguished had been tried in the British Museum in 1879.

A system of automatic switching from one candle to another, so as to introduce a fresh one on the first being consumed, was now under consideration and trial.

As regards dynamo-machines, M. Berly referred to the Gramme Alternating Current Machine* as being an excellent apparatus.

Gas engines were largely in use for driving the dynamo-machines, and worked very successfully.

In speaking of the progress of the light, M. Berly referred to the fabulous estimates which had been made from time to time as to the impossibility of burning a large number of lights except at an enormous expenditure of power and labour. The engine power (nominal) of the Thames Embankment lights was equal to 20, and this lighted four and a-half miles of footings. M. Berly predicted a great future for the electric light.

Mr. Mackenzie then explained a lamp invented by himself.

Mr. Heinemann gave further explanations of his lamp, and stated that it would burn for 30 hours, the brightness which existed was explained to be due to defective carbons, it being difficult at present to make them sufficiently hard in the ring shape.

Mr. Hedges next explained his lamp. This consisted of two carbons, the ends of which pressed at an angle against a block of lime which was kept continually rotating. The arc formed between the ends of the carbons, and the heat produced, rendered the lime incandescent, thus incensing the light.

Mr. H. F. Joel then exhibited an improved form of Wardermann lamp. In this arrangement the pencil of carbon pressed against a heavy disc of copper, the latter being hinged; the weight of the disc normally raised the grip of a clip which held the carbon-rod, the latter being pressed upwards by means of weights. As the rod consumed, the copper disc tended to fall down, thus releasing the clip and allowing the rod to rise. The whole arrangement of the lamp was such that the carbon-rod could be replaced with great ease when consumed. The current was turned off and on by means of a switch similar to an ordinary gas tap. When turned off the current was shunted through a resistance formed of carbon-rods. The resistance of the lamp when burning was 1·6 ohms, and the average resistance when not burning was 30 ohms. The faces of the copper clip were now formed of carbon, as it was found that a better contact was obtained by this arrangement. As regards economy, Mr. Joel stated that by recent improvements the economy had been nearly doubled, and the principle compared favourably with the arc lights.

In reply to Professor Ayrton, Mr. Joel stated that the resistance of the lamp was ascertained by the substitution method, that is to say, a resistance was inserted in the place of a lighted lamp, and varied until the original strength of current was obtained.

Mr. S. A. Phillips then explained Mr. Brockie's arc lamp, a full description of which is given on page 114 of the present number.

Mr. Conrad Cooke summarised the progress which

THREE MONTHS' EXPERIENCE OF ELECTRIC LIGHTING AT BLACKPOOL.*

By Alfred Haslam.

During this meeting I propose to place before you some particulars of the working of our electric lighting, together with the capital cost and the working expenses of the electric light during the three months it has been in use. I do not think it of interest and only tedious to you, but in the case would be generally, inasmuch as it is the only town in which electricity has been tried in the best advantage, and on a practical working scale.

In the beginning of August last year our town council unanimously agreed to light the central portion of their town with electricity, and for a length of about three miles, by means of the electric light, in a manner so entirely anything that had ever been attempted before; this system of lighting to be employed every season during the autumn months, and on days of festivity. The opening day was to be the 15th of September, and I may here say that they have accomplished their object of having created a complete success.

The committee appointed, together with my father, their gas engineer, first proceeded to inspect the various electric systems, lamps, and apparatus, at the exhibition at the South Thames Embankment lights; but we thoroughly satisfied were they that in all these there was nothing but what some large gas lamps would supersede, that they resolved to strike out the safer and experiment of having lamps capable of lighting, and employing four naked lights of 2,000 candles each, placed at the corners, we use as the roof of each of the two piers. The arrangement was therefore a considerable, 1000 yards long, and 50 feet wide, the two piers, at the Promenade are 250 yards apart, and these on the piers about 120 yards from the shore. The wires are placed in glass shot lanterns 60 ft. above the level of the roadway. This is necessary with the high voltage we employ, and is to be working after the contractors had completed.

The site selected as being convenient for the machinery was the Corporation Depot, situated, 400 yards from one end of the Promenade, and 250 yards inland. Here was built the engine and dynamo building, 60 ft. by 25 ft., and a boiler house, 40 ft. by 30 ft., fronting, which formed the entrance to the yard. The boilers were placed on each side of the entrance, and the engine and dynamo house at the end, and two boundary gear to prevent dust rising. Upon this were fixed, as they arrived, two portable 16 horse power engines and boilers, and at the opposite end were the electric machines, which also were fixed, all being driven from a countershaft which ran between them and the engines. From each of the six machines there were two wires, which passed from the one corner across the yard to the pier, to connect the lamps. You will, no doubt, wonder what the old machine was for. Well, at first the idea of the six machines had to perform the duty of producing their own electricity, but that duty we have taken from them by specially devoting a dynamo and this machine to that purpose solely, and this was found to be a most satisfactory plan.

The first difficulty we had to contend with was the laying of the wires inside the 2 in. and 3 in. cast-iron pipes, for having been decided to place them underground, hitherto from time. This proved to any easier, inasmuch as the way was in the pipes laid, and it was desirable to have as few joints as possible. It therefore cost as much to put the wires through as it would to make the trenches, as careful had we to be in order not to damage the insulation, and to keep off the water. The wires were therefore drawn in by an endless rope for us. A rope or two of wire or two of wire rope, a series of light winds set in, with their usual effect of bringing the wires through the water over the Promenade, to the commencement of valleys, last to the detriment of our work; but we soon got over this first location and pipes with any water. The wires at the time we time to stay, we perceived, and completed the whole of the work about the end of the year, and were ready for the preliminary trial to take place on Saturday, the 15th; but, alas! all our efforts were of no avail, for the insulation of the wires had yielded to the water, and it was quite useless for the purpose, so there was no alternative but to withdraw them. This we did on the following Monday evening, and drew out the whole of the wires, which were found to be lamp-posts. By the Saturday night we had temporarily connected the wires, and had two of the most successful trials that could be desired. By the following Monday morning we had collected together the most suitable poles in the town, and these we set to work and placed them up telegraph fashion, and secured the wires thereto with iron staples, these being found to be the most satisfactory. During the time the wires were being fixed experiments and trials were going on in the engine-house, and by Thursday, September 20, all was finally ready, and Mr. Wells were then

think with remarkable steadiness, considering the drawback of the unsteadiness of the engines.

It was hoped on that night we should be all right, but there were I beheld, from an elevated position, the lights dazzling down their twilight white beams on the vast crowd of at least 70,000 persons who had come to Blackpool to witness this grand event, to see the town put on new for one all annihilated. Well, I must say the gas could never figure when burning in the lamps where the electric lights were lit, of which a good many of you present were eye-witnesses, and I am sure you were pleased as the night's work, and no serious accident occurred, was finally extinguished, for it would have been useless to have had the lamps left all in darkness, which might have occasioned a very accident. As we got more accustomed to the eccentricities and freaks of our new and wayward sister, we gained in confidence because we found out how to apply the remedy. In nine cases out of ten the cause was the rock battling the carbons getting fast, and a man was usually on the look-out, and directly with the lamp to see the cause, when he did the keeper would ultimately the passing pebble and position was restored. Sometimes, however, more serious mishaps would occur, owing to the exposed position of the lights, and in the storm gales of wind and rain. The delicate working parts were affected by corrosion and damp, and in such cases there was no alternative but to take the lamp in for readjustment; as it had to remain extinguished for the time. This was a great loss to us, as it was a heavy paying light with it off. Upon all these occasions, however, we took out the spare lamp and substituted it, and thus we had very simplemindedly explained. The reason is this, that owing to all the circuits being of different lengths, and having different resistances, each lamp had to be accurately adjusted and tried in the test-room, with the current flowing all through the wire. Thus, supposing No. 1 lamp went out, and could not be got to work again; it is 1100 yards away, and No. 2 lamp is 1000 yards away, and the men in charge of people the two wires travelling, bring the lamp back, and set to work adjusting the spare lamp, and by the time this is all would require, say, half an hour; this is not all; it has and lost it up, the whole occupying 1½ hour, during which the light would be out, and would need another adjustment, who would afterwards have nothing to do, and some lights would never be visited although at least be always at work.

The mode of working which we have found to be the most advantageous is the following:—Our engineman and assistant look after the engines and boilers, while another very great attention in their staking, for the least simply pressure of steam will throw all the lights out of order. Another man is kept to sit the machines and keep all going right in their department, as also to look after all lamps that may require attention, and to see that all the six machines, but always one in abeyance, on which all the connections are made, and which we have suitable for this appliance. The hour for starting work is one o'clock p.m., and then the mode of procedure is as follows:—All the lamps men start out and fix the carbons in the lamps, clean the same, and load them up again. To the whole operation occupies 2½ hours if all is well. Occasionally a carbon will break in the lamp, and they have to be changed, which is a tricky sight, and this the men are very careful to do, as these babbs they take with them. On these occasions there have been a short fog every time. They now return to the machine room, clean the engines, and go carefully over the machines and belts, and then all is ready for lighting, which generally lasts five hours. We should have to go out this time, hence a second time if we had a light all night; therefore, with extra assistance, we have to go out a second time, and work until about four o'clock in the morning. This period of lighting is one that all is looked for, and is most in proper order all the lamps brought in, as well as to instruct the men in any repairs and alterations to be made. It is also very requisite to go round two or three times a week to see the arteries fixed to the lamps, as they are often a little, and to see that the current is working the lamps all right through.

By way of a little description of the work to be done, I think I could not do a better one than to give you the particulars of the cost of all this, and I will not over system in comparison with the others, so that you may see the proportion of the outlines between large lights and the small ones, comparatively speaking—those of the divided current, or Jablochkoff system. The following figures will show the amount of the capital account. These are the expenditure up to the 31st December, inclusive, as from the reports of Messrs. Siemens Brothers, and of the Metropolitan Board last May, but to the end of the year added the expenses which I find necessary to work their plant permanently, and this enhances the capital. Each item that is added is marked with an asterisk (*). It must be noted that the apparatus at Westgate was only temporarily fixed:

Capital Account.

Blackpool.

Six lights—2,000 candles available.

	£	s.	d.

Fuel, coke, and coal	0	0	6
Interest at 5 per cent.	0	0	1½
Repairs and maintenance, 10 per cent.	0	0	3*
Total	1	9	6

Now, it is a very difficult matter to put the proper interest to these tables, inasmuch as the longer the lights are burned the less is the cost per hour; but as I must compute it in some way, so as to arrive at the actual cost, I shall take our own as we intend to use it, or I will give it you as nearly as I can. We intend to keep our lights burning from seven to eight hours, and other than to burn from 5 to 5½ hours. The following calculations I wish me be made accordingly. In the preceding table you will note that we have two engines and boilers, and during the last week we kept the plant going with only one running; therefore, we shall compute favourably with the others in having reserve power, which is far better for safety than to be without such safety, and I may say it would be very necessary to have such power in this town, for on one occasion we were without any motive power for about a keeping up the illuminating power, and were fixed heavily for occasionally leaving part of the town in darkness.

Before closing my paper, I will say a word or two on some of the objects which our lights have produced in different states of its atmosphere, and conclude with a few remarks on the cost of working the electric light against our other allies. The four lights we have on the Victoria Promenade at Blackpool very well for a length of 1500 yards, but not exceeding that, having a decided diversity under them, and not so much midway between them, though amply sufficient for any requirement. If there had been six lights on this length, the effect would have been uniform throughout, and the same applies to the reliability of the light undoubtedly, as we should not have to have noticed particularly has been on some nights when the fog has been able to cut off the two ends of the lights at a distance inland of about 11 mile. This effect, I am of opinion, was caused by the reflection of the vapour from the clouds which I noticed hanging about in large masses pretty low on the horizon, and appearing like some kind of particular benefit to those of the fishermen, who have to go out to sea in the darkness, and enable them to find their lines to take fish, and they have many a time been able to see distinctly. The opposite effects are produced in a dense fog. I have only been able to see the lights at a distance of 100 yards, and I could see at the same distance one of the large 100-candle lamps that we have fixed in another part of the town, owing to the difference in the colour of the light.

The strong concentrated light of an electric lamp is very bad for the eyesight, and I would not recommend any ordinary eyesight to look at them. Occasionally a carbon will break in the arc, and the men employed, have had painful experiences in this result, although at the time we were unconscious we were being affected. While experimenting with the lights, I had a very painful time of it, and by this I do not mean that it is not very interesting, but after the novelty has worn off it will be no longer so. I have had, when I have set up and kept the lights going, and studied from light, as it is impossible to shut them, so painful are they. This result has been experienced by others, and I mention it in case of a great many who have visited the room to see the experimenting operations.

The great idea of the divisibility and distribution of electricity for lighting purposes is one that commends itself, having large houses and warehouses in view, and the principal streets, with small branches to each consumer—has not for a moment been thought of at the time of the electricians, though this is the plan the anxious public are waiting for. In my opinion the electric current have a storage for your supply, as with gas, where you create a large reserve, and, as it were, manufacture your own electricity, have those who require it simply turn on an outlet for the supply, and, by the great old law of gravitation, they get all they want from the stock, while a fresh supply is being made. This is the only way in which I can see our business, but we must be content to go on as we are, and must be consumed; for electricity must be made as it is used, otherwise it cannot be created, and as it moves it disappears. The same electricity does not move round again! A never-ending mystery, and one that puzzles us to know and makes room for more. Now, as it is impossible to store electricity in any considerable quantities, we can look at the object and see the difficulties, some as it is being generated; therefore, the greatest care must be taken to prevent any breakdown. This will be found a great disadvantage, assuming that a town is to be supplied, for it would seem that the apparatus would have to be constantly going in order to supply light when any consumer might at his option desire to avail himself of it during the day or night. It would be like working a gas works without holders for the supply, and this is a great objection to the system of speaking, namely, increased wear and tear and tear of retorts, plant, and now and then all darkness for a short time in the town, if a sudden stoppage took place on the mains, owing to a large establishment lighting up suddenly

tronic. The feature in electric lighting that not as yet shown itself, it being now at the end of the month of May of the year following that in which we lighted and put out the last consumer here that power left to like, which we will close up via right if he has to pay the bill, and another difficulty is care more pressed in the way of electric lighting for towns.

I am, of course, assuming that there is no difficulty in generating electricity, for it is mere mechanical power that is required. Nothing could be so easy, economical, and consequently, I might add, so certain. This leads me to say that the lighting systems of the present day, which are nearly all alike in their working, as regards dividing lights. The plan adopted is to put from half a dozen up to, say, twenty lights on one circuit—that is to say, one machine has twenty lights put on its wire from leaving the machine to coming back. The distance may be slight, or as long as your wire has conductivity to allow it to be, and the lights may be put on singly, or collectively, as you send through the number of lamps indefinitely; that is to say, the limits of the power of the machine are soon reached, and the more breaks or resistances you put on the circuit, so each of the lights is less in proportion, for the law of the flow of electricity is inversely as the resistance. Thus, let us suppose the current is represented by 100; now if you put on resistances equal to 100 more, you would cut in the internal resistance of the machine, which is equal to the best result of the Siemens machines, and you have doubled the resistance in the current; therefore, the total current is reduced to 50, of which the outside circuit has 25 available, that is to say, double the resistance, and the current is halved; treble the resistance, and the current is one-third as much. Therefore, you see soon the quantity the lights are reduced to, and you soon see the impossibility of doing as that you could not have small lights as successful as large ones. The same is the case with lamps burning by incandescence; you all know that it is only the resistance to the current—low that converts electricity into heat.

I really cannot see the reason for gas directors becoming alarmed lest they should be driven out of the field for lighting purposes, and I am afraid that the electricity, with its delicate working parts, and consequent extremely cut-off arrangements—all which are claimed to be simple in action, but which I am certain would soon get out of order if left to take care of themselves in any ordinary house—I am afraid, I say, that the out-off arrangements now in operation would be and occasionally, under ordinary usage, would be out of order, and consequently cause the loss of whole houses. For public museums, large halls, and for lighting the main thoroughfares at large towns, where known light is wanted that is near the meridian necessary by most local authorities, there, I say, gas and electricity will come into competition; but I can't opinion that our main thoroughfares are well illuminated during business hours by the sun light, although where the gas is in the street lamps it is usually lighted for about an hour or half an hour's wasting of money in the morning, as many of the results power being every 60 yards or so apart. After business hours there is, comparatively speaking, not anybody out of doors, and gas keeps are ready for the purpose of giving light. The scope which electricity has is necessarily very limited, there not being so very many large spaces which will need to be lighted up so brightly as to only consume the light of the sun, moon, and stars. There is a larger field open for it in the transmission of motive power, in which electricians may reap more remunerative employment for their labours if they will accomplish their grand idea of utilising the tides, and the Falls of Niagara, in supplying the general method of supplying motive power for the great industries of the world.

working of metalliferous mines has ceased to be attended with the profits which were formerly obtained from them, chiefly on account of foreign competition; but if it were possible to effect the reduction of the ore raised by a cheap fuel on the spot a great revival of the mining industry would ensue At the present time mining in Cornwall and Devon would be considerably advanced were fuel for smelting purposes available in the locality at a cheap rate; at present the coal for the purpose has to be conveyed at a considerable expense from a distance, or, on the other hand, the smelting products have to be conveyed to the neighbourhood of the coal-pits, the expense of carriage in either case being heavy. Now, in both Devon and Cornwall the fuel exists, not in the form by which it is commonly known, but it exists in the numerous streams and waterfalls, and in the tide which surrounds their iron-bound coasts. The conversion of motive power into electricity and heat has been proved to be possible. Will some scientific and commercial genius practically apply the knowledge which has been obtained? The theoretical possibility of the idea we have suggested is, we imagine, unquestionable; its practical possibility, we think, is as certain.

Whilst advocating the application of electricity to the smelting of metalliferous ores by means of power converted into heat by electricity, we would by no means insinuate that the reduction of the ores must necessarily be effected in this way. The science of electro-metallurgy daily shows that many may be reduced from their salts by the electric current; cannot it effect the reduction of metals from their natural earthy condition by a process equally simple with that of electro-plating, and do it in an economical manner? The motive power necessary to effect the results exists in inexhaustible quantities; it only wants to be applied. Let electro-metallurgists and electricians ponder the question out, as we feel certain they will do in time, and another triumph will be won by means of electricity.

CROMPTON'S ELECTRIC LAMP.

Its general principle this lamp possesses but little novelty; it is rather a refined and well designed arrangement adapted from old patterns, but the improvement effected in the mode carrying out of first principles renders the lamp one of the best yet designed.

There are two distinct movements in the lamp, by one the carbons are separated to a definite distance, and by the second; they are allowed to approach together until checked by a slight increase in the current, consequent thereon. A

two hundredths of a millimetre; the feel, therefore, is practically continuous and causes the light to be proportionally steady.

The pinion into which the wheel, a, gears is not fixed to the wheel, c, but is connected to the latter by a ratchet wheel, so that the rod, n, can be drawn up when it is required to insert a new carbon, without turning all the wheels in the train.

The course of the current through the electro-

(3)

magnet and carbons is quite simple; thus, the current, entering at w, passes through the electro-magnet, a, direct, thence to the frame of the apparatus and the upper carbon, and from there to the lower carbon and back to the dynamo machine.

The screw, d, when screwed down presses the strap, r, against the brake-wheel, A, and prevents it from turning; this is only required for security during transport.

THE NEW SAWYER ELECTRIC LAMP.—This lamp," says the *Scientific American*, "burns upon the incandescence principle, and the material employed is nitrogen gas," if it be not very different from that used in the Bouligaire or the old Sawyer-Mann lamp exhibited some years ago. The gas itself is contained within a globe two inches in diameter and ten inches high, sealed at the bottom to a brass socket, which, while adhering perfectly to the globe, is yet sufficiently elastic to compensate for the unequal expansion of the two. It entered only at a temperature of 200° Fah. The globes are charged by the process invented some time ago by Thomas B. Stillman, which is so simple in its details and so rapidly operated that a single workman can prepare fifty lamps per hour at a cost of about thirty cents, in such a manner that according to Stillman's calculation, the amount of atmospheric air remaining is only an infinitely small fraction of the normal quantity. The cost of the nitrogen is stated at eight-tenths of one cent, and that of its purification as one and one-fifth cents; the total cost of recharging a lamp, when the nitrogen is exhausted or becomes mixed with air, being, inclusive of the wages of the workmen, two and three-fifths cents, against a cost of seventy cents for the process usually employed. "The carbon" pencil, seven inches in length and about three thirty-seconds of an inch in diameter, is fed upward as fast as disintegration takes place at the point of contact, by means of a regulator, which will be substituted by an automatic feeder as soon as the arrangement can be perfected. Mr. Sawyer says that one of these pencils, used for five hours a day, will last at a minimum calculation from his experiments, not less than ninety days, and, at a maximum, for two years. The cost of the pencil is a trifle less than two cents, and the cost of replacing and recharging with nitrogen also and three-fifths cents. The leg of asbestos and the large spiral conductors at the base of the carbon, which were distinguishing features of the Sawyer-Mann lamp exhibited about a year ago at No. 92 Walker-street, have been discarded. Two small steel rods take the place of the latter. "The globe, which is not unlike the chimney of an ordinary kerosene lamp in general appearance, is imbedded in a nickel-plated base, which may be highly ornamented or not, according to the taste or means of the user. Photometric tests, it is said, have been made with a 600 candle-power dynamo, such as is used by the companies for the same purpose, and each light was registered as equal to twenty-seven of the ten-inches standard candles, or a little more than twice the value of a four-foot gas burner, which usually registers from ten to twelve standard candles. Mr. Sawyer claims that his system of distribution is entirely novel and original, but declines for the present to give a description of it, the patents not having been as yet secured. The regulator, we are told, is based upon the plan used by the old Berlin house of Siemens Brothers, by which only such a volume of current is supplied as is necessary to overcome the resistance. The light is readily toned down by a glimmer-burning solution in the wall. In its capital purposes this light is much like gas. It is yellow, steady, and soft, and does especially well for reading in the day. It has none of the blue rays incident to the voltaic arrangement, and the shadow cast by intervening objects is softened and mellowed at the margin. For practical purposes it is intended that the power of each lamp shall not exceed that of two ordinary gas jets."

[It is stated that seven lamps are operated upon one circuit worked by four horse-power. The economy of this system does not appear to be marvellously great. Seven lamps of 25 standard candles each, or 1925 candles in all, for four horse-power, is not a very wonderful achievement.—The Eng. Edit.]

5 ft. gas burner. = 10 to 12 candles. (?)

ever saw, namely, New Rush or Kimberley. It is simply a collection of canvas tents and sheds of galvanized iron, the larger being used for stores and drinking saloons, canvas theatres, and churches of various denominations. Here dwell the diggers, men of every nation under the sun, each individual attracted together by the glitter of the diamond. The Celestial has not, strange to say, yet his food in three yet to receive his kicks and halfpence smilingly; but one may see any day on the streets or in the inns a Lascar cooking next to a Frenchman, a Yankee with a New Zealander, an Irish patriot talking drinks with a Japanese, and even a Russian on friendly terms with a Turk. When all sorts of men meet like this for a common object far from home and old prejudices, they rely only on their merits, and friendly and forget differences of race and creed. A friendly goodwill makes the heterogeneous elements work together amicably. We found the diggers both hospitable and kind, although, perhaps, rather addicted to taking and giving drinks. We were heartily welcomed by them all; for, rough natives as they were, they had the feeling that we had somehow brought them nearer by six days to their old homes.

ELECTRIC LIGHTING IN AMERICA.

[The following letter deserves careful reading. It is not often that we can commend the scientific enterprise of newspaper correspondents, but this communication to the *Standard* of the 13th inst. is worthy of reproduction, and we can only hope that the writer may continue to send us good material in the future.—ED. *E.*].

NEW YORK, APRIL 2.

The value of the small incandescent light invented by Mr. Edison last December continues to be much discussed. This lamp was a carbonized filament of bristol board burnt in the form of a horse-shoe, enclosed in a hermetically sealed glass bulb, three inches in diameter, and heated by a current of electricity. The resistance of the filament was claimed to be 100 Ohms. When the public exhibition was given on Fourth-street there were forty-five of these lamps in use in the buildings and streets of Menlo Park, the light being maintained by three dynamo-electric machines.

I visited the shops a few days ago, and had a long conversation with Mr. Edison. While still confident that his lamp is to be ultimately an unqualified success, Mr. Edison surprised me by saying that only two of his paper carbon lamps were then in existence. The rest, nearly 300 in number, had been destroyed by the action of the electric current, one after the other. From some cause, which no one understood at first, the platinum conducting wires would, after a short period of satisfactory service, suddenly grow hot in some lamp. The glass bulb then would crack, and the pressure of the air outside would burst in the glass at two points, and the carbon would then consume almost instantly. This accident occurred to one of the lamps, finally, while Mr. Edison had it under observation. He discovered that the contact between the ends of the paper carbon and the conducting wires was not perfect. A vehicle was formed there, the wires grew hot, and the lamp was destroyed before his eyes. He sought then to remedy the trouble by copper-plating the ends of the carbon, in order to make a more perfect contact with the conducting wires. This expedient was not successful, and the paper carbons kept going out. Sometimes they would burn out within ten minutes without any rupture of the glass bulb. A record duration of each of them was seven hours. Some lasted that time.

Two of these inventions are still in use, and are lighted every night. One is in the store, the other in a house within the new enclosed for one thousand seven hundred hours. It is the defects of the light-are to cure, and that he will yet solve the long-agitated problem of electric illumination of small buildings. This lamp which holds out so well is now being made the subject of special study, and I regret to say that no one who looks at it admires Mr. Edison's opinion. Within the glass bulb of this lamp there is now a deposit of fine black powder, which is thickest in the lower part of the bulb, and globe of a gaslight. This phenomenon indicates the early destruction of the lamp. It reveals the fatal and inevitable defect of carbon as a material for a small incandescent light. It shows that even in the remarkable vacuums produced by the mercurial air pump carbon will volatilize. This has been the trouble invariably with all this class of inventions in America so far. No carbon vacuum lamp has been produced here the interior of which would not be covered with a deposit of volatilized matter after being in use for a few hundred hours. Rupture of the burner has invariably followed the appearance of the deposit in the course of time. Mr. Sawyer, the rival of Edison, has come definitely to the conclusion that this sort of thing cannot be prevented, and he has abandoned all hope of perfecting a permanently durable lamp of this class.

Edison has now been brought face to face with the true character of the problem before him. Nature has supplied only two materials for an incandescent light. He has tried these both, and finds both defective. Platinum melts, and carbon volatilizes. The only question seems to be, how long can carbon be made to last? With a view to ascertaining the truth he has begun a new series of experiments. A Professor at Harvard University has sent to him fifty different varieties of fibres of grasses and woods, obtained from all parts of the world, some of them having been obtained for the University during the explorations of Agassiz in South America. He is trying the value of these for carbons. The object is to obtain a filament more tenacious naturally than paper, and one which shall be fruitless throughout its whole length. It is found to be durability to have the filament of unequal size. If at any point in the length of the carbon the diameter is smaller than elsewhere the force of the electric current concentrates there and causes a rupture. Mr. Edison finds that manila fibre is the best of the fifty submitted to him. It is remarkably strong, even, and elastic when carbonised, and gives as good a light as paper. Its existence in bigger than that of paper. About twenty lamps with this material for the burners have now been made. I saw about a dozen of them lighted at Mr. Edison's shops a day or two ago. There is nothing noteworthy about them, except that it takes more power to make them give a sixteen-candle light than it did the paper carbon lamps. When fully incandescent they had the same beauty and brilliance of this class of lights in general. How many can be maintained per horse-power is not known. They would be beautiful lights to introduce into dwellings, and could they be depended upon they would make a great sensation. But I now begin to believe that neither they nor any other small incandescent carbon lamp will ever be introduced to dwellings to any very extensive degree. Edison's people will not be are willing to submit to some inconvenience for the sake of obtaining a light which will not consume the air. There is no reason to believe that the manila carbons will last much longer than the paper carbons. Experience has taught that lesson. People who use the Edison lamps, therefore, must expect breakages, sudden extinction of lights, and other annoyances of a similar character, in fair proportion of which will occur on occasions when they will be most inconvenient. It is doubtful whether if any one would wish to purchase additional purity of air in houses at such a cost. I am certain that no one in New York does, nor will any one here give any encouragement to household illumination with these lamps until they are proved to be proof against accident.

Mr. Edison is greatly vexed at the growing popular incredulity in regard to his reiterated assertion that a satisfactory system of illumination has been perfected. He recently asked Professor George F. Barker, of the Edison Electric Light Company, at Philadelphia; Professor Rowland, of the John Hopkins University at Baltimore; and Professors Brackett and Young, to investigate the subject and announce the result of their inquiries to the public. This committee of scientific gentlemen spent a few days at Menlo Park the early part of the present month, and a night before last, Professor Barker made a report in the form of a lecture at Philadelphia. He had a number of the carbon lamps in the hall, and used an electric current of one-horse, consuming twenty-one cubic feet of gas per hour per horse-power, to generate the current. The lecture was an unfavourable exposition of the qualities and modes of generating the electric light. It contained no new and important information. It was, in fact, a disappointment to all who were hoping for a clear criticism of the value of Mr. Edison's achievements. Of the durability of the lamps at Menlo Park nothing definite was known, as only one of them had lasted forty-one hours less than six hundred hours. The fact that disaster had overtaken them all except two was duly referred to. Of the economy of the light it was admitted that, so long as gas can be made for eighty cents per thousand cubic feet, the electric light can be produced no cheaper. Professor Barker repeated the claim which has been made at Menlo Park, that ten sixteen-candle lights can be produced per horse-power, but no demonstration of this was made on the platform. Mr. Edison hopes to obtain ten good lights per horse-power, but he does not do it yet. It is upon his ability to do that that the whole claim of superior economy of the incandescent light is based, and why this unsupported assertion should continually be made by himself and his friends surpasses all comprehension. It is doing him great injury in the estimation of all practical men. It is the well-known failure to annihilate natural

THE ELECTRIC LIGHT.

EXPERIMENTS are in progress at the North Shore Mills, Liverpool, under the direction of Mr. Ward, engineer of the British Electric Light Company, with the Ambre incandescent lamp, which is said to possess several special advantages. The light is contained in a globe hermetically sealed, and, as the carbon burns the light becomes feebler from exhaustion with the air, they are not subject to combustion, or the illumination is so slow as to be almost imperceptible. The lamps is simple and effective. It is self-adjusting, devoid of mechanical appliances, and, as the carbon points are not actually consumed, it will remain illuminated for many hundred hours. The avoidance of any renewal of the carbon points is an obvious advantage, as is the fact that the new system admits of a complete subdivision of the current of electricity.

ABSTRACT OF PATENTS.

2301. ELECTRIC LIGHTING, *R. Werdermann.*—*Dated* [illegible]

The upper electrode is screwed by a stump connected to an arm placed in a horizontal position, and provided to a sliding piece on a fixed vertical bar. In order to adjust the light, the upper electrode is screwed further under the light, and a portion of the rays pass through it, and are reflected upward upon a small deflector fixed above the electrodes.

2322. ELECTRIC LAMPS, *C. D. Abel.*—*Dated* 11th June, 1879.—(*A communication.*)—(*Not proceeded with.*) 2*d.*

The two carbon electrodes are carried by two pistons, plungers, or fluids contained in two closed vessels filled with liquid, in communication with each other, the relative heights of the liquid in the vessels and the weight of the pistons and arms projecting therefrom carrying the carbons being so proportioned that the piston carrying the upper carbon will tend to descend in its vessel, causing the liquid to flow therefrom into the other vessel, and thereby raising the second piston with the lower carbon.

ELECTRICAL TELEMETER.—In the *Revista Militare* is described by M. G. Le Cordier de Tréhérin, of the French Navy, for the purpose of determining at any moment the distance of a movable and inaccessible object, two sides of a triangle are indicated by a telescope through which the object is observed from station A, and by a base line, say 1,000 metres in length, between this station and another station B, at which the object is observed through a second telescope. On the base line and at a distance, say of one metre from the terminal point, about which moves the telescope at A, is pivoted a pointer which, by means of a succession of currents produced whenever the telescope at B is moved, is consequently maintained exactly parallel with this instrument. It will be seen that this pointer gives at station A the third line of a triangle exactly 1,000 times smaller than that formed by straight lines from the inaccessible object C to the extremities of the base line between the stations A and B. The pointer may thus be made to indicate on a scale at A the exact distance at any moment of the movable object, whenever the observers at A and B are *both* at their posts. The apparatus for the transmission of the currents from B is somewhat similar to that in the alphabetical instrument of Messrs. Siemens; whilst in the receiver at A a shaft carrying an endless screw is influenced by two electro-magnets, so as to move a toothed wheel, to the axis of which is attached the pointer which is maintained parallel with the direction of the telescope at B.

ENIGMATIA.—The *Operator* says, "The opinions of scientific men in Europe as to the ultimate success of Edison's light seem much divided." We thought otherwise; and it still seems to us that the scientific opinion of Europe is practically unanimous, and is that Edison has failed. In fact we have not heard of one solitary individual possessing any scientific standing in Europe who has expressed the opinion that Edison has succeeded.

mittee of the Society of Telegraph Engineers or British Association should be appointed to consider these points, and decide authoritatively the exact nature of the future to be employed.

Electrical Notes.

ON THE EFFICIENCY OF EDISON'S ELECTRIC LIGHT.

By Professor H. A. Rowland of the Johns Hopkins University, and Prof. G. F. Barker of the University of Pennsylvania.

The great interest which is now being felt throughout the civilized world in the success of the various attempts to light houses by electricity, together with the contradictory statements made with regard to Mr. Edison's method, have induced us to attempt a brief examination of the efficiency of his light. We deemed this the more important because most of the information on the subject has not been given to the public in a trustworthy form. We have endeavoured to make a brief but complete test of the efficiency of the light, that is, the amount of light which could be obtained from one horse-power of work given out by the steam engine. For if the light be economical, the minor points, such as making the carbon strips last, can undoubtedly be put into practical shape.

Three methods of testing the efficiency presented themselves to us. The first was by means of measuring the horse-power required to drive the machine, together with the number of lights which it would give. But the dynamometer was not in very good working order, and it was difficult to determine the number of lights and their photometric power, as they were scattered throughout a long distance, and as this method was abandoned. Another method was by measuring the resistance of, and amount of current passing through, a single lamp. But the instruments available for this purpose were very rough, and so this method was abandoned for the third one. This method consisted in putting the lamp under water and observering the total amount of heat generated in the water per minute. For this purpose, a calorimeter, holding about 11 kil. of water, was made out of very thin copper; the lamp was held firmly in the centre, so that a stirrer could work around it. The temperature was noted on a delicate Bandin thermometer graduated to 0°1 C.

As the experiment was only meant to give a rough idea of the efficiency within two or three per cent., no correction was made for radiation, but the error was avoided as much as possible by having the mean temperature of the calorimeter as near that of the air as possible, and the rise of temperature small. The error would then be much less than one per cent. A small portion of the light escaped through the apertures in the cover, but the amount of energy must have been very minute.

In order to obtain the amount of light and eliminate all changes of the engine and machine, two lamps of nearly equal power were generally used, one being in the calorimeter while the other was being measured. They were then reversed and the mean of the results taken. The apparatus for measuring the light was one of the ordinary Bunsen instruments used for determining gas-light, with a single candle at ten inches distance. The candles used were the ordinary standards burning 120 grains per hour. They were weighed before and after each experiment, but as the amount burned did not vary more than one p. c. from 120 grains per hour, no correction was made.

As the strips of carbonized paper were flat, very much more light was given out in a direction perpendicular to the surface than in the plane of the edge. Two observations were taken of this in the photometric power, one in a direction perpendicular to the paper, and the other in the direction of the edge, and we are required to obtain the average light from these. If I_0 is the photometric power perpendicular to the paper, and I that of the edge, then the average λ will evidently be very nearly

$$\lambda = I_0 \int_0^{\frac{1}{2}\pi} \cos\alpha \sin\alpha \, d\alpha + I \int_0^{\frac{1}{2}\pi} \sin^2\alpha \, d\alpha,$$

$$\lambda = \tfrac{1}{2} I_0 + \tfrac{\pi}{4} I.$$

In the paper lamps we found $I = 1_0$ nearly; hence $\lambda = \frac{\pi}{4} I$, nearly.

The lamps used were as follows:—

No.	Kind of carbon.	Size of carbon.	Approximate resistance when cold.
880	paper	large	147 ohms.
881	"	"	147 "
850	"	small	170 "
869	"	"	154 "
817	fiber	large	87 "

The capacity of the calorimeter was obtained by adding to the capacity of the water the copper of the calorimeter and the glass of the lamp and thermometer. The calorimeter and cover weighed 0·103 kil. and the lamps about 0·035 kil.

First experiment, No. 201 in calorimeter and No. 880 in use.

might remain in one town, and with his battery send a locomotive and train to any distance required.

It would seem from the above that the idea of railway car propulsion by electricity was projected in this country more than thirty years before Mr. Siemens' motor was introduced to the public.

THE ELECTRIC RAILWAY AN AMERICAN INVENTION.

On page 137 of the present volume of the Scientific American will be found translations and descriptions of Siemens' electrical railway motor, which was operated at the Berlin Exhibition in 1879. Since that publication our attention has been directed to a similar plan described in the Scientific American as long ago as September 25, 1847, which reads as follows:

"Mr. Lilly and Dr. Colton, of Pittsburg, Pa., have invented a new method of railway propulsion, which is both novel and ingenious. The machine is a small locomotive, and is placed upon a circular railway, around which it is driven by electricity. The power is applied not to the locomotive, but to the track, in a very curious manner. Two currents of electricity, negative and positive, are applied to the rails, and by them communicate to the engine. The latter is provided with two magnets, which, by a process of alternate attraction and repulsion, drive the car over the track. A piece of lead is placed on the locomotive, making in all a weight of ten pounds, and on the application of the battery, the machine moved with astonishing rapidity up a plane inclined about five degrees. Heretofore the propelling power had been used on the car itself—in this instance, however, the power is placed on the rails, and an engineer

ON THE DYNAMO-ELECTRIC CURRENT AND CERTAIN MEANS TO IMPROVE ITS STEADINESS.*

By C. WILLIAM SIEMENS, D.C.L., F.R.S.

The subject of my paper relating to the early conception by Dr. Werner Siemens of the dynamo-electric principle, and to the subsequent discovery of gradation of electro-magnetic power, which I claimed in the subject presented, the one by Sir Charles Wheatstone and the other by himself, to the Royal Society in February, 1867. The machine then designed by him, and shown in operation on that occasion, is again brought forward with a view of indicating the progress that has since taken place in the construction of dynamo-electric machines, particularly those by Gramme and Siemens-von Alteneck. The paper next points out certain drawbacks to the use of these machines, both of them being subject to the disadvantage that an increase of external resistance causes a falling off of the current; and that, on the other hand, the short circuiting of the outer resistance, through contact between the carbon electrodes of an electric lamp, very much increases the electro-motive element of the machine and the power necessary to maintain its motion, giving rise to rapid heating and destructive sparks in the machine itself.

An observation in Sir Charles Wheatstone's paper is referred to, pointing to the fact that a powerful current is set up in the shunt circuit of a dynamo-electric machine, which circumstance has since been taken advantage of to some extent by Mr. Ladd and Mr. Brush, in constructing current generators.

The principal object of the paper is to establish the conditions under which dynamo-electric machines worked on the shunt principle can be made to give maximum results. A series of tables and diagrams are given, the results of experiments conducted by Mr. Lundell, electrician, employed on the author's works, which lead up to the conclusion that, in constructing such machines on the shunt principle, the resistance on the rotating helix has to be considerably reduced by increasing the thickness of the wire employed, and that on the magnets has to be increased more than tenfold, not by the employment of thin wire, but by augmenting the length and weight of coil wire employed.

The results of this mode of distributing the resistances is summarized as follows:—

1. That the electromotive force, instead of diminishing with increased resistance, remains at first nearly, and then more slowly towards an asymptote.

2. That the current in the outer circuit is actually greater for a unit and a half resistance than for one unit.

3. With an external resistance of one unit, which is about equivalent to an electric arc, when thirty or forty webers are passing through it, 2·44 horse-power is expended, of which 1·29 horse-power is usefully employed, proving an efficiency of 53 per cent., as compared with 45 per cent. in the case of the ordinary dynamo-machine.

4. That the maximum energy which can be demanded from the engine is 2·6 horse-power, so that but a small margin of power is needed to suffice for the greatest possible resistance.

5. That the maximum energy which can be injuriously transferred into heat in the machine itself is 1·3 horse-power, so that there is no fear here of destroying the insulation of the helix by excessive heating.

6. That the maximum current is approximately that which would be habitually used, and therefore the economy of heating brushes are quite capable of transmitting.

Hence the author concludes that the new machine will give a steadier light than the old one with greater economy of power, that it will be less liable to derangement, and may be driven without injury at a speed by a smaller engine; also that the new machine is free from all objection when used for the purpose of electro-deposition.

This construction of machine enables the author to effect an important simplification of the regulator of arc lamps, consisting him to dispense with all wheel and clockwork in the arrangement. The two carbons being pushed onward by gravity or spring power are clocked laterally by a pointed metallic abutment, situated at such a distance from the arc itself that the heat is only just sufficient to cause the gradual wasting away of the carbon in contact with atmospheric air. The carbon holders are connected to the iron core of a solenoid coil, of a resistance equal to about 50 times that of the arc, the ends of which coil are connected to the two electrodes respectively. The weight of the core (which may be varied) determines the force of current that has to pass through the regulating coil in order to keep the weight in suspension, and this in its turn is dependent upon the resistance of the arc. The result is that the length of the arc is regulated automatically, so as to maintain a uniform resistance signifying a uniform development of light.

* Abstract of a Paper presented to the Royal Society.

lometer; capacity of calorimeter = 2·163 + ·060 t + ·007 t² = 2·169 kil. The temperature rose from 18°·28 C. to 22°·11 C. in five minutes, or 3°·76 F. in one minute. Taking the mechanical equivalent as 772, which is about right for the degree of this thermometer, this corresponds to an expenditure of 3,898 foot pounds per minute. The photometric power of No. 880 was 17·5 candles maximum, or 13·1 mean, λ.

When the lamps were reversed, the result was 3,540 foot pounds for No. 880, and a power of 13·5 or 10·1 candles mean.

The mean of these two gives, therefore, a power of 11·6 candles to 3,719 foot pounds per minute for 11·6 candles, or 10·0 candles to the horse-power.

To test the change of efficiency when the temperature varied, we tried another experiment with the same pair of lamps, and also used some others where the radiating area was smaller, and, consequently, the temperature had to be higher to give out an equal light.

We combine the results in the following table, having calculated the number of candles per indicated horse-power by taking 70 per cent. of the calculated value, thus allowing about 30 per 70 per cent. for the friction of the engine, and the loss of energy in the magneto-electric machine, heating of wires, &c. As Mr. Edison's machine is undoubtedly one of the most efficient now made, it is believed that this estimate will be found practically correct. The experiment on No. 817 was made by observing the photometric power before and after the calorimeter experiment, as two equal lamps could not be found. As the latter was round, it gave a nearly equal light in all directions as was found by experiment.

Mean number of candles per indicated horse-power.	Mean gas per hour per candle per indicated horse-power.	Mean gas per hour per candle per electrical horse-power at 70 per cent.	Mean number of candles per electrical horse-power.	Energy per minute in foot pounds.	Rise of temperature in degrees F.	Capacity of Calorimeter in pounds.	Photometric power: Maximum. The Edison Light

To the Editor of the Scientific American:

With this I send you the report of Profs. Brackett and Young on the efficiency of Mr. Edison's machine for generating electricity.

As undoubtedly comparisons will be drawn between the figures there given and those which have been given by Dr. Hopkinson for the Siemens machine, an analysis of his figures is not out of place. In *Engineering* for May 9, 1879, a full report of the tests of Dr. Hopkinson may be found.

He assumes, in calculating the work which is done in the circuit, that agreably Daniell's cell has an electromotive force of 1·075 volts, though this form of cell is the weakest of any. In the calculations which the makers of other machines have rated the efficiency of their machines, 1·079 volts has been assumed as the electromotive force of a Daniell's cell. As the work varies with the square of the E. M. F., its figures for work in the current must be multiplied by $\left(\frac{1\cdot079}{1\cdot075}\right)^2$ = 0·919; that is, 91·9 per cent of the work given by his figures should be taken in comparing the Siemens with other machines. I take experiments 9, 10, 11, and 12 as representing very nearly the conditions of practical use. These show, according to his figures, 2·803 erg-tens in the current to 4·101 erg-tens given the machine by the belt, or 91·5 per cent as the efficiency of the machine. Using the correction mentioned, 84 per cent will be the true number. Taking the resistance of the machine as 0·083 ohm, which it would be after running a short time, these experiments show 23 per cent in outside work; that is, of 9·55 horse power given the machine by the belt, 2·20 horse power was effective outside.

Profs. Brackett and Young show 70·7 per cent convertel, and 62·9 available outside.

I hope this statement will be sufficient to end the discussion into which I was drawn some time since regarding Mr. Edison's machine. He then claimed that ⅔ of the power in the current could be made available; now tests show ¼ of the energy in current are available.

It is not "childish," then, to make an armature with about one eighth of an ohm resistance, as was claimed by others at the time.

Yours, FRANCIS R. UPTON.

REPORT OF COMPARISON BETWEEN THE FRONT AND EDISON DYNAMOMETERS, AND UPON THE EFFICIENCY OF THE EDISON DYNAMO-ELECTRIC MACHINE, BY PROFS. C. F. BRACKETT AND C. A. YOUNG, OF THE COLLEGE OF NEW JERSEY, PRINCETON, N. J.—EXPERIMENTS MADE APRIL 3, 1880.

FIRST COMPARISON BETWEEN THE DYNAMOMETERS.

The lever arm of the Prony was held down by the action of a spring balance applied at division 12, corresponding to a virtual circumference of 15 feet. The weight of the balance was 0·41 pounds, which is to be added to all its readings. The balance was read by Mr. Upton. After the experiment, the Edison dynamometer, immediately no work, as read by Prof. Brackett, indicated the mean of five readings, ranging from 920 to 923; 921·2 pounds. During the experiment, the readings were made by Prof. Brackett and recorded by Prof. Young.

Duration of test, 10 minutes.

Number of revolutions of Prony shaft, determined by counter, 5,604.

Number of revolutions of main shaft, 1,893.

Mean indication of Edison dynamometer, deduced from Prof. Brackett's ten readings, varying from 920 pounds at beginning to 923 at end of experiment, 921·7 pounds.

From this, taking the mean reading of the zero, 224·2 pounds, we have $\frac{924\cdot2 - 224\cdot7}{2}$ = 348·25 pounds.

Mean tension on Prony arm, 9·011 pounds, varying gradually from 10·01 pounds at beginning to 7·00 pounds at end of experiment, including weight of scale.

Work registered by Prony, 9·011 (lb.) × 12 (ft.) × 5,604 (rev.) = 812,460 ft. lb.

The diameter of main pulley is 38 inches.

The angle between belts of Edison dynamometer is taken at 45°. Assume K = $\left(\frac{88}{12} \times \sin.22°\right)^2$ = 10·7297. Then the Edison dynamometer registered K (ft.) × 1889 (rev.) × 34·23 (lb.) = 693,880 ft. lb. That is, the Prony recorded 86·6 per cent of the work carried by the Edison dynamometer.

The comparison does not seem to us satisfactory on account of the considerable change in the conditions during the experiment.

SECOND COMPARISON.

Constants and observers as before.

Duration of test, 4 minutes.

Number revolutions of Prony, 2,281.

Number revolutions of main shaft, 770.

Mean tension on arm of Prony, 11·85 lb., varying from 11.00 to 10·97 in seven readings.

Initial reading of Edison dynamometer (mean of five), 204·2.

Final reading of Edison dynamometer (mean of five), 204·2.

Mean during comparison, 341·97.

(Mean of seven readings, varying from 910 to 913 lb.)

Work according to Prony, 11·85 (lb.) × 12 (ft.) × 2,281 (rev.) = 810,880 ft. lb.

Work according to Edison instrument, K (ft.) × 770 × $\left(\frac{204\cdot2 - 911\cdot57}{2}\right)$ = 833,360 ft. lb.

In this comparison the Prony registers 98·2 per cent of work indicated by the Edison dynamometer.

We regard this test as fairly good, the conditions having been very constant, and the outstanding difference of 0·8 per cent being reasonably accounted for by slip of belts and friction of journals between the two dynamometers.

TESTS OF THE EFFICIENCY OF THE DYNAMO-ELECTRIC MACHINE.

During both these tests the thermometer of the calorimeter and the Edison dynamometer were read as often as every minute, and great pains were taken to keep the water thoroughly stirred. The calorimeter was a galvanized iron vessel, 16·42 inches in diameter and 21½ deep.

The wire coil was wound upon a light wooden frame, so constructed as to serve as a very efficient stirrer.

The thermometer was an excellent instrument, by James Green, graduated to fifths of a Fahrenheit degree, each degree being about three-sixteenths of an inch in length.

Prof. Brackett read the dynamometer.

Prof. Young read the thermometer and made the records.

Mr. Upton and others, the speed of the main shaft and the indications of the high resistance galvanometer in the laboratory.

CONSTANTS.

Weight of calorimeter (empty)	23·93 lb.
Heat capacity of same (taking specific heat at 0·112)	2·63 lb.
Weight of wooden frame	2·71 lb.
Heat capacity of frame (s. taken at 0·30)	1·71 water lb.
Weight of wire coil (541 turns, each turn weighing 2·64 grammes)	2·72 lb.
Heat capacity of wire (s., 0·10)	0·27 water lb.
Resistance of coil in calorimeter	1·720 ohms.
Resistance of leading wires taken as ¼ of coil	0·0357 ohm.
Resistance of wire on reversing armature	0·140 ohm.
Resistance of coil on field magnets	1·470 ohms.

FIRST TEST.

Total weight of calorimeter with contained water and everything in place	197·6 lb.
Hence from preceding data the heat capacity of whole	172·77 water lb.
Temperature of air	72·2°
Temperature of water at beginning	63·8°
Temperature of water at end	80·7°
Gain during experiment	16·7°
Duration of experiment...10m. 50s.	10·833 m.
Dynamometer at beginning (fred)	204·2
Dynamometer at end (fred)	205·
Mean dynamometer zero	204·6
Speed of main shaft, beginning	174 per min.
Speed of main shaft, end	170
Mean	172
Mean reading of dynamometer during experiment	771·75 lb.
(Varying from 790 to 781, 10 readings.)	

E. M. F. of current maintaining field was 61 divs. of galvanometer, on which 108 d. corresponded to 16 Daniell cells, *i.e.*, E. M. F. = $\frac{61}{108} \times 16 \times 1{\cdot}079$ volts.

Energy expended on driving armature, as indicated by dynamometer = K (ft.) × 172 (rev.) × 12·833 (min.) × $\left(\frac{204\cdot6 - 771\cdot75}{2}\right)$ = 2,844,600 foot pounds.

Energy expended on field of force $\frac{6}{5} \times \frac{48{\cdot}25 \text{ (ft. lb.)}}{1{\cdot}47 \text{ (ohms)}} \times 12{\cdot}833 \text{ (m.)} \times \left(\frac{61}{108} \times 16 \times 1{\cdot}079\right)^2$ = 19,634 foot pounds.

Hence, total energy expended, 2,864,234 foot pounds.

Energy Realized.

a. In calorimeter = 172·77 × 10·7°	2,237,426 ft. lb.
b. In leading wires ¼ of above	7,453 ft. lb.
c. In armature ¼ of calorimeter, 172	181,393 ft. lb.
Hence, total energy realized	2,426,147
Total available (*a* + *b*)	2,231,845
Hence,	
Total efficiency	84·5 per cent.
Total available	78·2 per cent.

Remarks.

During this test the driving power was about 6½ horse power; the electromotive force of the field current, 0·27 volts, giving a current through the magnet wires of about 4½ webers; and the current developed by the machine was about 45 webers through a total resistance of 1·805 ohms.

SECOND TEST.

Total weight calorimeter and contents	200·00 lb.
Hence by preceding data, heat capacity =	172·27 water lb.
Temperature of air	71·4° to 71·9°
Initial temperature of water	62·3°
Terminal temperature of water	72·9°
Gain	10·7°
Duration of experiment	9 minutes.
Speed of main shaft, beginning	176 per m.
Speed of main shaft, middle	171 per m.
Speed of main shaft, end	177 per m.
Mean	175·33
Dynamometer reading before exp.	205
Dynamometer reading after exp.	205
Mean dynamometer zero	205
Mean reading of dynamometer during the experiment (6 readings, between 645 and 655)	656

Electromotive force of field (by high resistance galvanometer) = $\frac{143}{108} \times 16 \times 1{\cdot}079$ = 14·001 volts.

E. M. F. of dynamo current = $\frac{656 - 205}{2} \times 23 \times 1{\cdot}079$ = 10·05 volts.

E. M. F. of armature of dynamo current broken, $\frac{200}{51} \times 20 \times 1{\cdot}079$ = 129·71 volts.

Energy Expended.

a. In driving armature according to dynamometer, K × 175 (rev.) × $\frac{656 - 205}{2}$ = 3,827,500 ft. lb.

b. In maintenance of field of force, $\frac{6}{5} \times 24{\cdot}25 \text{ (ft. lb.)} \times 9{\cdot}3 \text{ (m.)} \times \left(\frac{14{\cdot}001}{1{\cdot}47}\right)^2$ = 72,150 ft. lb.

Hence,

Total energy expended	3,899,730 ft. lb.

Energy Realized.

a. In calorimeter, 172×12·27	2,359,700 ft. lb.
b. In leading wires ¼ of above	7·033 ft. lb.
c. In armature ¼ of *a*	183·930 ft. lb.
Total energy realized (*a* + *b* + *c*)	2,451,163 ft. lb.
Available (outside of machine) (*a* + *b*)	2,367,233 ft. lb.

Remarks.

As a check we may compute the total efficiency from the galvanometer reading and the resistance: Energy developed, 4·01 (ft. lb.) × 9 (m.) × 10·05 (volts) × 1,866 (ohms) = 2,500,000 ft. lb.

The discrepancy is fairly explained by the defective insulation of long wires leading to the galvanometer, as it was raining at the time.

During the experiment the driving power was about 8¼ horse power, and the current was 67·4 webers (according to galvanometer, 54·4).

Even with this current the spark at the commutator was very trifling.

SUMMARY.

	Total Efficiency.	Available Efficiency.
According to first test	84·5 p. c.	78·2 p. c.
According to second test	84·5 p. c.	78·2 p. c.

The Prony dynamometer is connected to the Edison dynamometer by a belt from the same countershaft, which is also belted to the electric generators. If we should assume the correctness of the Prony, and that the loss in the transmitting power between the Edison dynamometer and the other of the armature was only the same as between the two dynamometers, the above numbers would have to be increased in the ratio of 100 to 87·8 (see above), and we should have:

Total efficiency	96·7
Available efficiency	89·0

C. F. BRACKETT,
C. A. YOUNG.

Princeton, N. J., April 10, 1880.

ON ELECTRIC LIGHTING.*

(Second Paper.)

By Dr. Hopkinson, F.R.S., of London.

Dynamo-Electric Machines.—Since the date of the Bakerian lecture, which contained the following paper, I have published the results of experiments similar to those described in this, now as well as then, with the object of testing, and, if possible, improving, the theory of former papers, and such as that shown on Fig. 1 of the former paper, and now reproduced, with slight alterations, in Fig. 1. Here

any abscissa represents a current passing through the dynamo-electric machine, and the corresponding ordinate represents the electromotive force of the machine for a certain speed of revolution. This current is supposed to pass through it. It will be found (1) that with varying speed the curve, or one proportional to it, remains unchanged in any of its features, except as represented by the speed; (2) that the electromotive force does not increase indefinitely with increasing current, but that the curve approaches an asymptote; (3) that the earlier part of the curve is, roughly speaking, a straight line, until the current attains a certain value, and that at that point the electromotive force has reached about four-fifths of its maximum value; (4) that the current is positive for all positive values of the electromotive force of the machine, a very small changeover in the resistance with speed of engine constant, or in the speed of the engine with resistance constant, causes a great change in the current. For the reason such a current, which at the same for all speeds of revolution, since the curves for different speeds differ only in the scale of ordinates. To called the "exciting current" of the machine. The exciting current for the machine exhibited in Fig. 1, where the lower line represents a current for a speed of 600 revolutions per minute, instead of 752. The resistance, varying as electromotive force is given by the slope of the line O *r*.

The current

which must therefore be constant; and it will be seen that the line cuts the upper curve at a point corresponding to a current of 15 webers, and the lower at a point corresponding to a current of 9 webers only.

Mr. Crompton and Mr. Alexander Siemens (Wolverhampton), Nov., 1879) have experimented carefully on a Gramme machine at various speeds, and with various external resistances. The resistance of the machine was 0.37 ohms. Their results are summarized in a Table at the end of their paper, which gives the current passing, with resistance in circuit from 1.75 to 200 Siemens units, and at speeds from 70 to 800 revolutions per minute. In the curves, Figs. 2, 3, and 4, number No. 1 represents the relation between electromotive force and current, as deduced from some of their observations; the points marked are plotted from their Table, making allowance, where necessary, for difference in speed. The curve, as actually constructed, is for a speed of 800 revolutions; at this speed it will be seen that the electromotive force attained about 96 volts; the critical current, when the resistance in circuit was 1.75 Siemens units, was the total resistance of 1.8 ohms. Up to this point will be seen practically; exactly as was the case in the Siemens machine examined by the author, where the resistance was 4 ohms, and the speed 720 revolutions.

The results of an elaborate series of experiments on certain dynamo-electric machines have recently been published by Mr. Schuckert, of Nuremberg. One of the machines investigated was a Gramme, differently coiled, but substantially similar to that tried by the author in 1879. It is described as having 24 divisions of the commutator; 336 coils on the armature, with a resistance of 0.4614 Siemens units; and 512 coils on the magnets, with a resistance of 0.3663; making a total resistance of 0.7502 Siemens units, or 0.7127 ohms. The curve, Fig. 2, No. 2, gives the relation of electromotive force and current produced in a speed of 750 revolutions per minute, the circuit speeds ranging from 650 to 1000 revolutions. The maximum electromotive force appears to be probably 76 volts, and the critical current 10 webers: which is the same as in the author's first experiments on a similar machine.

In the course of the same paper Mr. Schuckert describes a Siemens machine, which he has differently coiled, but used as an exciter for the differential magnet machine. It has an internal resistance of 0.74 ohms, of which 0.355 is in

* Paper read before the Institution of Mechanical Engineers.

† See ENGINEERING, vol. xxvii, page 393.

the series coils on the magnets. The machine is marked to run at 1150 revolutions per minute, the following Table gives, for a speed of 1000 revolutions, the total resistance, current, electromotive force, and force per unit of current. The horse power per unit of current is also given.

Curve No. 3, Fig. 2, gives as usual the relations of electromotive force and current. From this curve I will

Experiments on modified Alfred Varley Dynamo-Electric Machine.

Resistance.	Electric Current.	Electromotive Force.	Horse Power developed as Current.
Ohms.	Webers.	Volts.	HP.
2.624	4.52	12.2	0.07
2.761	10.8	27.0	0.39
2.898	14.1	37.0	0.69
1.291	18.1	36.1	0.88
1.668	19.8	37.2	0.99
1.579	20.0	36.6	1.01
1.565	22.8	39.3	1.20
1.440	24.7	40.0	1.32
1.145	32.2	41.5	1.79

be seen that the critical current is 11.2 webers, and the maximum electromotive force, at the speed of 1000 revolutions per minute, is 46 volts. Interpolations for this machine are made in exactly the same manner as in the experiments on the modified-steel machine, using the galvanometer, but omitting the experiment with the rheometer (compare Table, page 401, ENGINEERING, vol. xxvii.)

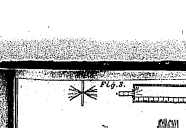
The time required to develop the current in a Gramme machine has been examined by Herwig (Wiedemann, Ann., 1879). He established the following facts for the machine he examined. A reversed current, having an electromotive force of 0.9 Grove cells, sufficed to destroy the residual magnetism of the machine completely. The time required was as far as possible isolated; there is no way, however, of time to get up the current then when the machine was in its usual state. The time was required to get up to the current when the external resistance was great, then when it was small. With ordinary resistance the current required from 2 second to 1 second to attain its maximum.

Calculation of the Electric Efficiency.—The measurement of the light and of the electric arc presents certain peculiar difficulties. The light of the arc is very unsteady, and that of a standard candle, by means of which it is usual to express luminous intensities. The statement, without qualification, that a certain electric lamp and machine give a light of a specified number of candles, is therefore wanting in definite meaning. A red light mixed with propriety be said to be any particular multiple of a green light; nor can a candle of a light of a certain colour be said to be equivalent to be a multiple of another, unless the proportions of the colours in the two lights are the same. Mr. Varley (Proceedings of the Royal Society, March, 1859) has given the results of measurements of the red, blue, and actinic light of electricity, in terms of the red, blue, and actinic light of a standard candle. The fact that the electric light is a very different thing from the light of gas or of a candle, has long been known, but has not, so far as I am aware, been expressed in definite terms.

Again, the emission of rays from the heated carbons and between electromotive force and current, as deduced from some of their observations; the points marked are plotted from their Table, making allowance, where necessary, for difference in speed. The curve, as actually constructed, is for a speed of 800 revolutions; at this speed it will be seen that the maximum electromotive force attained 96 volts; the critical current, when the resistance in circuit was 1.75 Siemens units, was the total resistance of 1.8 ohms. Up to this point will be seen practically; exactly as was the case in the Siemens machine examined by the author, where the resistance was 4 ohms, and the speed 720 revolutions.

The results of an elaborate series of experiments on certain dynamo-electric machines have recently been published by Mr. Schuckert, of Nuremberg. One of the machines investigated was a Gramme, differently coiled, but substantially similar to that tried by the author in 1879. It is described as having 24 divisions of the commutator; 336 coils on the armature, with a resistance of 0.4614 Siemens units; and 512 coils on the magnets, with a resistance of 0.3663; making a total resistance of 0.7502 Siemens units, or 0.7127 ohms. The curve, Fig. 2, No. 2, gives the relation of electromotive force and current produced in a speed of 750 revolutions per minute, the circuit speeds ranging from 650 to 1000 revolutions. The maximum electromotive force appears to be probably 76 volts, and the critical current 10 webers: which is the same as in the author's first experiments on a similar machine.

In the course of the same paper Mr. Schuckert describes a Siemens machine, which he has differently coiled, but used as an exciter for the differential magnet machine. It has an internal resistance of 0.74 ohms, of which 0.355 is in



at 2 of the powerful source of light which it is desired to measure. The intensity of the light from this image will be less than that of the actual source by a calculable amount; and when the distance of the lens from the light is suitable, the reduction is such that the reduced light becomes comparable with that from a standard lamp. The photographic (?) arc seems a very efficient reducer. It cuts the focus, to cut off stray light. One of these is shown in Fig. 3, to act as a small aperture. It is easy to see that this diaphragm will cut off all light entering from a direction other than that of the lens or reflector.

Does it do so, that observations may be made in broad daylight, or any source of light. If a dark screen be placed behind it. The long lens of the Fig. 3 is 1 foot 1 inch long, is fixed with other—the slide, shown dull red—the slide, now sold with a flelak, which reflects a great deal of the light incident at a small angle. This is used as a dark chamber, in which the intensity of the image formed by the lens is compared with the intensity of light, by means of an ordinary Bunsen's photometer E, sliding on a graduated bar.

Mr. Dalleyzer kindly made and tested the mirror for the author; he can therefore rely upon the accuracy of its curvature and thickness. It is plano-convex, the convex side being towards the source of light. The curvature is exactly 1 in. radius and the thickness is 0.1 in. It is made of Chance's patent crown glass, of which the refractive index for the D line is 1.5127, see section 1.127. The focal length *f* is therefore 1.1322 inches.

Let *u* denote the distance of the source of light from the curved surface of the lens, and *v* the distance of the image of the source it from the posterior focal plane. Neglecting for the moment the reflection at the surface of the glass,

the intensity of the source is reduced by the factor $\left(\frac{v}{u}\right)^2$.

But $\frac{1}{u} + \frac{1}{v} = \frac{1}{f}$, or $\frac{u+v}{uv} = \frac{1}{f}$; hence the factor of reduction is $\left(\frac{1}{u+1}\right)^2$. The effect of absorption is so small a thick-

ness of very pure glass may be neglected; but the reflection at the surfaces will cause a loss of 0.2 per cent., which must be allowed for. This percentage is calculated from Fresnel's formulæ, which are extremely accurate for glasses of moderate refrangibility, and for moderate angles of incidence.

Suppose, for example, it is required to measure a light of 20 candles at a distance of 10 feet. The image of 20 in. 1 ft. will be reduced in the ratio of 1 to 1.1 and becomes a conveniently measurable quantity. By transmitting the light through glasses both the light from an electric lamp and that from the standard, a rough comparison may be made of the red or green or blue of the electric light with the red or green of the standard.

A reflecting photometer, in which a lens is used in a manner similar to that described above, is known as Sugg's "Lighthouse Illuminator," is described in the Journal of the Society of Arts, 1879, page 1. In that instrument a lens is used with any standard light. Messrs. Ayrton and Perry described a diagonsing photometer with a common lens at the meeting of the Physical Society on December 19, 1879 (Proc. of the Physical Society, vol. iv, part 1, page 1). Lenses possess, however, an obvious advantage in having a focus, and in which a diaphragm to cut off stray light may be placed.

Efficiency of the Electric Arc.—To define the electrical conditions of an electric arc, two quantities must be elected—the current passing, and the difference of electric potential at the ends of the two carbons. Instead of either one of these, we may, if we please, state the ratio of the two.

The current, and all the resistance of the arc, is therefore known, the resistance which would replace the arc without changing the current. The ratio of the two forms the electric resistance in ohms; for this use of the word, see the definition of electric resistance rests, is quite unique of the electric arc; and on the other hand, for a given material of the electrodes, a given distance between them, and

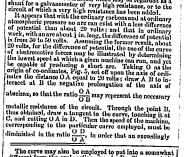
a given atmospheric pressure, the difference of potential at the two sides of the arc is practically constant. The product of the difference of potential and the current is of course equal to the work developed in the arc, and, divided by the work expended in driving the machine, may be considered as the efficiency of the whole combination. If the difference of potential be given in volts, and the current in webers, the difference between the two sides of the arc may be measured by the number given by the method in the previous paper, by an electrometer, or in other ways. The current may be measured by an electrometer, by a suitable

electro-dynamometer, or best of all, in the author's opinion, by passing the whole current through a coil in the form of a very small tangent galvanometer, which may be regarded as a shunt for a galvanometer of high resistance placed in the circuit of which a very high resistance has been cut out.

It appears that with the ordinary carbons used at ordinary atmospheric pressure no arc can exist with a less difference of potential than about 39 volts; and that in ordinary circumstances, as in Table 1 in page, the difference of potential is from 39 to 50 volts. Assuming the former result, about 39 volts, for the difference of potential at the arc curve of electromotive forces may be illustrated by determining the lowest speed at which a given machine can work, and will be capable of producing a steady arc. Taking O as the origin of coordinates, Fig. 5, set off upon the axis of ordinates a distance O *a* equal to 39 volts; draw A B to perpendicular at B the negative prolongation of the axis of abscissæ, so that the ratio $\frac{B\,O}{B\,A}$ may represent the necessary

metallic resistance of the circuit. Through the point B, thus obtained, draw a tangent to the curve, touching it at C, and meeting O *a* in *a*. Then the ordinate C D, corresponding to the particular curve employed, must be divisible by *a* O; in order that an exceedingly

The curve may also be employed to put into a somewhat different form the explanation given by Dr. Siemens at the Royal Society, respecting the self-regulating quantity of the electric light as produced by ordinary dynamo-electric machines. The operation of self-regulation is as follows:—If the carbons when the current is greater than a certain amount, and the distance of the arc is thus initially the carbons are in contact. Through the origin O, Fig. 6,



draw the straight line O A, inclined at the angle represented by the resistance of the arc, and draw from A a curve resembling the curves at A. The absolute of the point A represents the current passing when the carbons are separated from operating. Let O N represent the current to which the lamp is to be adjusted, and draw N P parallel to O *a* together with the curve A P. Through N draw the ordinate N P, meeting the curve in P, and the point P is parallel to O *a* draw a horizontal P D, meeting the curve in D. If the point D is to the right of D, or further from the origin, the arc will increase; if D is to the left of D, or nearer to the origin, the carbons will go on parting, till the current suddenly falls and the light goes out. If D is although to the right of D, is very near to it, a very small increase in the current will cause the carbons to re-approximate to the normal distance, giving stability to the light by causing the electro-magnets of the machine, by a shunt circuit, instead of by the whole current.

The success of burning more than one regulating lamp in series depends on the due regulation of the electro-magnet, excited by a high-resistance wire connecting the two terminals of the arc. The author has found that a speed 150 revolutions per minute is the most convenient for burning, as in the ordinary Siemens machine, and consequently the author has found it necessary to resort to expedients of the following rule for determining the number of lamps in a system of electric lighting in which the electric arc is used. We are being neither exceptionally long nor exceptionally short. Measure the difference of potential of the arc, and also the current passing through it, in volts and webers respectively. Let the product of these two numbers be called by *W*, in the horse power developed in that arc. It is also known that the difference between the horse power developed in the arc and the horse power expended to drive the machine must be absolutely wasted, and has been expended in heating either the iron of the machine or the copper conducting wires.

The Brush Electric Light.

EVERYTHING relating to electric light, its cost, its advantages, its drawbacks, its actual [illegible] is a profitable substitute to gas for lighting up large factories or railway termini, is naturally an open question; yet as [illegible] the working of the light under the [illegible] test of actual use for about a year and a half, we found both instructive and suggestive. The following information is taken from a report on the use of the Brush Electric Light in the Riverside Worsted Mill, at Providence, R. I.:

"The first machine was set up and started about the 20th of February, 1879; its success was instant and complete; so much so that this machine was accepted and another ordered at once. This second machine was started in March, when a third was ordered by telegram, which was set up and running early in April. In September we ordered two more, which are both now running, making in all five of the largest machines, having capability for [illegible] lamps, which are now regularly lighted; nearly all of our principal rooms. We could not have a severer test than we give them, as our mill runs night and day, six days per week, and we have a full force of men at work. Mr. Brush's claim of 'a dollar's worth of repairs on, say, one machine or lamp, in a year,' we find to be correct; it is strong and steady, and white; it is steadier than that afforded by both oversewer and belt; so much so that we doubt if we could get along now with the help if we were to return to the old gas lighting; certainly we should not get as good work, nor so much of it. The air of the room, too, shows a very marked difference. In our weave room, with its one hundred and fifty gas lights, the air became almost stifling after midnight in the summer; and that [illegible] opposite of the men showed how they felt it. With the electric light there is no such trouble, as the air is as good as in the daytime and noticeably cooler."

The question of the relative cost of electric and gas light is disposed of as follows:

"In reply to some changes proposed by setting up new machinery, all our eighty lamps now run on the same circuit as at first; but by actual count we have seventy-one lamps permanently placed and three displace five burners and seventy-eight gas-burners; that is, there are five hundred and seventy-eight burners already placed that would be lighted were the electric lights stopped. Estimating these burners at six feet per hour, we should use 3,468 cubic feet of gas per hour, costing, at $2 per thousand cubic feet, $6.93 per hour. The actual cost of the electric light is as follows:

The lamps consume carbons.....	$0.02
Power and belting.....	.50
Interest on cost of machines, say $12,000.....	.30
Time to run machine and lamps..	.33
Oil, wear and tear, etc.....	.07
Total cost per hour.....	$1.20

Making a saving of four dollars and seventy-three cents per hour, and this saving, for the three thousand hours the machines are in the year, is $14,190, and nearly pays for the machines. These figures are approximate, as the number of cubic feet burned for several nights to get the exact consumption of each lamp, and number of the gas-burners in use, had them, getting a strong jet foot to each burner."

The object of Mr. Edison's improvements, it must not be forgotten, is to adapt the electric light to household uses. The success of the new illuminating system for large buildings is already an accomplished fact.

EDISON'S HORSEPOWER LAMP VERSUS GASLIGHT.

THE last number received of the *Scientific American* contains a report, by Professor Henry Morton, Professor Alfred M. Mayer, and Mr. R. F. Nichols, on "Some Electrical Measurements of Mr. Edison's Horsepower Lamps," in which they say that much has been written and said within the last few months about Mr. Edison's lamp, but that the public has been furnished with only a few meagre and disjointed facts, and no connected statement bearing in the way of precise and reliable statement concerning the simplest primary facts, a knowledge of which would give the means of estimating both the scientific and commercial status of this widely discussed invention. It was, therefore, with great pleasure that they found themselves placed in possession of one of the horsepower lamps of recent construction; and to satisfy themselves as to the real facts of the case, they soon made a series of observations and measurements, by means of which they have reached a clear conception of other points which have been made at the same time but imperfectly observed, as a correspondent on this subject addressed to Mr. Edison did not evoke a reply, they were obliged to content themselves with the one lamp as a subject of experiment. They, however, remark that the behaviour of this lamp under the tests, and the agreement of the results with information otherwise obtained, convinced them that it was at least a fair specimen of the lamps of this form so far as completed by Mr. Edison.

After detailing their mode of determining the amount and character of the electric current needed to operate the lamp efficiently, they describe their arrangements for measuring the resistance of the incandescent pencils in actual use, and omitting different amounts of light; also the quantity of current flowing under the same conditions. Having done this, they had all the experimental data required for the determination of the energy expended in each case. This is found by multiplying the square of the number of amperes by the resistance in ohms, the product being the energy expended in each burner. That is, if a current of 1 ampere flowing through 1 ohm of resistance, with an energy of 10 dynes, power 10 dynes each, or 100 units power in the aggregate.

The photometrical measurements were in all these cases taken with the carbon loop at right angles to the axis of the photometer; and this was, of course, under the worst circumstances for the lamp, for, on turning the loop around so as to bring the carbon loop with its plane parallel with the axis of the photometer, the illuminating power was found to be greatly increased—the light was greatly diminished, so that it was reduced to almost one third of what it was with the loop sideways to the photometer disc. The illuminating power, in its best position, was found as 24 candles; and in the worst, as 8 candles. The average or general illuminating power was, therefore, reckoned, as above, at 16 candles.

In running this, that a Siemens or Brush machine were employed in general practice, a current of 10 webers would be obtained (as has been shown by numerous experiments) with a loss of about 40 per cent. of the mechanical energy applied to the driving-pulley. This would represent 13 horse power in all. Now, therefore, since 1 horse power would have to be applied to the pulley of the machine, so that when this loss in transformation had been encountered, there should be 1 horse power of electric energy produced. This would call for 17 horse applied to the pulley of the dynamo-electric machine by the steam-engine. Now, to produce 1-horse power in a steam-engine of the best construction, about 2 lbs. of coal per hour must be burned, and therefore 13-horse power 3 lbs. of coal must be burned. On the other hand, 1 lb. of gas will yield 5 cubic feet of gas, and there, besides, a large amount of coke, to say nothing of other residuals, which would represent practically also, a certain value. Now, between "steaming" and "gas-making" coal, we find that 2 lbs. of coal is taken to take 5 lbs. of gas coal as the equivalent of 5 lbs. of gas, which, if burned in a gas-burner of the best construction, would give from 30 to 32 candles; or 160 to 170 candles in the aggregate. There would therefore be 32 dozen lamps producing 192 candles, and gas-burners producing 160 to 170 candles, with an equivalent expenditure of fuel.

In regard to this result, the report concludes: "If such apparatus and system can be perfected with equal facility and economy, this would, of course, show startling power of the electric light; but when, in fact, everything in this regard is taken into account, electric light—which demands costly motive machinery, and that of a most delicate kind; requires much skilled management; shows more liability to disorder, loss and waste; and reveals an utter lack of the storage capacity which we have in the gas; efficiency, convenience, and economy in gas—then we see that a relatively trifling economy disappears, or ceases to have any controlling importance in the practical relations of the subject."

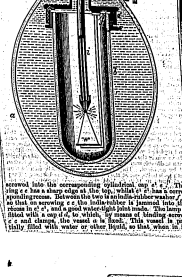
ELECTRICITY v. GAS.—At the twenty-first annual meeting of the Manchester District Gas and Coke Company, held last week, Mr. Clever, of Blackpool, [illegible] Months' Experience of the Working of the Electric Light." He described the experiment he had the result of the [illegible] trial of, the new illuminating power as a means of lighting up the Blackpool promenade and piers, then entered at some length into the question of cost, and stated "that the capital expended in the case of Blackpool was £2,800. The working expenses were £3 6s. 10d. per night of five hours. With respect to the question of electric lighting in general, he entertained no fear that it would ever supersede gas, pointing amongst other things to the difficulty which must inevitably be occasioned, if gas were used as a general illuminating power, by the fact that electricity could not be stored, but must be produced as required; so that the apparatus would have to be continuously at work for the benefit of consumers who might require light during the day or night. He also referred to the difficulty of increasing the number of lights beyond a certain number in one circuit, as that small lights could not be produced as economically as large ones. He saw no cause for alarm, for he was sure that electricity, with its delicate automatic cut-off arrangements, which would soon get out of order, would never be used for the illumination of dwelling-houses and such-like purposes, though for lighting public squares, large halls, &c., it might enter into competition with gas. In the discussion which followed, the ex-president (Mr. Newbiggin) expressed his opinion that electricity was simply an expensive luxury in lighting. Several members spoke of the failure, or comparative failure, of experiments which they had witnessed, and the President referred at some length to an experiment made in illuminating a cousing shed in Messrs. Crossley and Sons' woollen mills, Halifax, by means of the "Brush" light. Sixteen lights, with a total illuminating power equal to 2,000 candles, were in use, all supplied on one circuit by one machine of 14-horse-power. The light was steady, and was not affected as regards the other lamps by the accidental extinguishing of one or more of the number. The capital outlay was equal to a fixed annual charge of £75, to which £25 must be added for attendance. The cost of the 16 lights was 1s. 9¼d. per hour, and they displaced 200 gas burners, consuming 1,000ft. of gas, costing 8s. per hour. Calculating upon the average number of hours that a mill was lit up in a year the cost of the electric light would be £19, in addition to the fixed charges of £100, or a total of £119, while the gas would cost only £45." Some of the information given this week in other columns will cause readers to doubt the value of these expressions of opinion.

THE ELECTRIC LIGHT AT ALDION MILLS.—The electric light is now in practical work at Aldion Mills. It is supplied by the Anglo-American Electric Light Company (Limited), Hatton-garden, London; and on Thursday night, and again last night, their engineer exhibited the light, by the kind permission of Messrs. John Crossley and Sons (Limited), to a number of visitors. The devotion of Mr. L. J. *Crossley* to electrical science is too well known to need mention here, and the public are, no doubt, indebted to him for this opportunity of seeing the light in practical work. Messrs. Crossley, we understand, have adopted the system on trial. It is applied only to the carding and combing shed, a building with an area of 200 feet by 136, and hitherto lit by 230 gas jets. The light is generated by a "Brush" dynamo-electric machine (so called from the name of the inventor), and there are 17 lamps (any one of which can be extinguished without regard to the rest) in a single circuit. The circuit of the lamps, too, can be extended to any length up to 10 or 12 miles from the machine—an important consideration where one machine and engine are to be used for several buildings or rooms a long way apart. By a regulating attachment to the machine, any less number of lights than the maximum can be used, absorbing proportionately less power. Each light is in a globe, the lower part of which is transparent, and the upper part semi-transparent. Fifteen lamps were used on Thursday night, taking the place of the 230 gas lights. The effect was very fine indeed. The light was steady as that from gas, with the exception of that from two lamps, which was a very little unsteady. The arrangement of the lamps, hung perhaps three yards from the floor, caused the light to be equally diffused over the place. The writer asked a workman for his "honest" opinion about the light. The workman said he liked it much better than gas, first, because it enabled him to see work better which required his close attention, and, secondly, because there was no gloom in any part of the shed. Some of Messrs. Crossley's carpets were shown in order that the effect on colours might be noticed. It is easy to distinguish any colour by the electric light. As adjoining shed was lit with gas, and as both sheds could be seen at once, the superiority of the electric light needed no further demonstration. Halifax gas, good as it is, appeared a dingy, tawdry yellow. But the merits of the light itself are well known; what the public wish to know is something about the cost. On this point we have made inquiries, supplemented to by before our readers some facts, obtained from an impartial source, which have the merit of being compiled continually in the buyer's interest. To light the shed at Aldion Mills with gas, 1,265 feet are consumed per hour, the cost being about 9s. 11d. This does not include gas fittings and repairs. The first cost of electric lighting is rather serious. Including all plant, it has been, in Messrs. Crossley's case, about £2000. To arrive at the working cost, a cautious manufacturer would reckon on this 5 per cent. interest, 5 per cent. depreciation, and 2 per cent. for wear and tear. The machine requires 14 indicated horse-power to work it. The carbons, which are consumed by each lamp at the rate of 2 inches an hour, cost 4d. per foot. The only additional outlay is for labour, and in Messrs. Crossley's case a man will probably be employed not more than half an hour a day. Here, then, is the basis of a calculation which each can make for himself. The figures point to this general result, that where a large area is to be lit, and where the number of hours during which the light will be required per year is considerable, the cost is much less than that of gas. Where gas is used in small quantities it will, for the present, be the cheaper means of lighting; but this leaves out of question the much greater illuminating power of electricity.—*Halifax Courier.*

BROUGHAM AND ANDRE'S ELECTRIC LAMP.

Two almost simultaneous and quite various improvements that are being made in the electric lamp—the substitution of magneto machines, *vice* existing Clarke's or Holmes', and the way when the electric light is viewed simply as an experimental success, and is made fit to be of the character of a more effective of artificial illuminants. The improvements which we have describe at long way to remedy the defects which have retarded the practical use of the electric light. Electric lamps objectable to the account of many things concerning the eye are, broadly speaking, divisible into two classes—a combination of the and those relying on incandescence and the failure of two. We have named merits of the incandescent light is the each kind. Each undoubtedly preferable in the competitor of steadier, and in all respects more suitable to the competitor of the arc, as it is in the case of Messrs. Siemens and Co., Manchester at the works of Messrs. Peter Brotherhood, Limited, Sheffield, the improvement effected by the Hon. R. C. D. Brougham will place it before any other lamp on this principle now in use.

The principle of the improvement will at once be seen when we state that it reduces the consumption of carbon to about 1220*lb.* per hour, whilst a similar carbon burnt in a lamp open to the atmosphere burns about 6lb. per hour, the cost in carbons being thus reduced to one-forty-eighth of what it would be in an ordinary lamp. This is probably a maximum reduction, inasmuch as the carbons in ordinary lamps are of a larger diameter, those used in the Anglo-Brougham lamp being only 7mm. diameter. The improvement consists in surrounding the lamp, or a portion of it, with a separate cover of glass containing water or some other suitable liquid. In the accompanying diagram *A B* is the glass globe of the lamp proper, and the surrounding vessel containing the liquid. The shape of these vessels is immaterial, and we have chosen that for simplicity if the lamp is to be used in the ordinary position, but if it is to be used in a non-conformist, such as plotter of Paris. These tubes are connected to the two terminals of the battery by the binding screws *D m*. The outer tube *g g* is in electrical contact with the positive terminal by means of metal W. The inner tube *l* contains the carbon rod which rests upon the metallic wedge and falls down by its own weight, and that of a small weight placed on the top of the carbon, but within the tube. No doubt the light is also partially in incandescence of the carbon, and partially in the formation of an arc. The cap *a* on the top of the tube *g g*, through which the inner tube passes, is of vulcanite or of some non-conducting material. Round the top of the lamp globe *b b b* is a metal cylinder to be



screwed into the correspondent stimulation cap, *c c*. The ring *c c* has a sharp edge at the top, which serves to cut the rubber washer which makes the lower water-tight joint, so that by screwing *c c* the bulb-holder is fastened and the carbon is *c*, and a good water-tight joint made. The lamp is filled with a cap of *c*, by which, by means of binding screws *c c* and clamps, the vessel *a b* fixed. This vessel is pre-ably filled with water or other liquid, so that, when in the proper position the liquid rises above the cap *c*, thus excluding the consumption of air into the lamp an impossibility. So long as the liquid in *a* is above the cap *c*, no atmospheric air can enter the lamp globe *b*, a light joint is obtained, and at the same time the heat from the lamp is carried off or dispersed and the light more or less diffused.

Lamp Light.
Arc Was Superior

A section of the new electric lamp, produced by M. Jamin, member of the French Institute and Professor of Physical Science at the Polytechnic School, was printed in the *Journal* for July 22, 1870, and since that time the inventor has been engaged in improving his lamp. The new apparatus was exhibited lately at the works of the Compagnie General d'Eclairage Electrique, Paris, to a large assembly of representative persons.

Around the great hall in which the meeting occurred were 40 lamps, each containing three candles. The lighting and relighting of the lamps was effected instantaneously. This result is obtained, without touching the apparatus, by simply establishing or re-establishing the communication. Should one of the lamps become accidentally extinguished, the other lamps would not be affected by the accident. Moreover, the carbons are consumed, so that when burn as usual, the intensity of their light being unaffected by it. should one of the candles be consumed, another is instantly and automatically brought into play. The intensity of the light is completely under control, and may be graduated or regulated at will, from its full power down to the light of a sixth-light. The inventor states that the lamp may be made to burn 80 hours without any hesitation.

Mons. Jamin has stated the question of cost in this form: "Suppose a given quantity of gas to yield a certain amount of light, and that quantity to be consumed in one eight-horse power gas engine, which drives one of the small Gramme machines, sufficient for sixteen Jamin lamps, the light obtained is ten times that which would have been produced by the direct combustion of the gas itself."

It is further stated that a series of experiments have proved that one horse power will give light equal at least to as much, if not more, than fifty Carcel lamps. At the concluding meeting the whole force of a twenty-horse power engine was brought into play, and the effect declared equal to at least two thousand Carcels.—*Jour. Soc. Arts.*

Brush Electric Light at Portsmouth, Eng.

The "Inflexible" dock at Portsmouth dockyard was lighted up on the night of the 7th inst. by means of the electric light. The dock is 416 feet long by 110 feet wide, and about 39 feet deep, and the object of the trial was to ascertain whether it were possible, in time of urgent need, to work an ironclad after dark, or to continue the work of completing her for sea throughout the night.

The apparatus used was one of Brush's dynamo-machines, consisting of eight magnets and four powerful electro-magnets, and driven at a speed of eight hundred revolutions per minute. The lamps were also constructed on the Brush principle. Sixteen of these lamps were placed in the engine-room, electro-plating shop near at hand, where the generating machine was fixed. The experiment is reported to have been quite successful.—*Journal of the Society of Arts*, Lon., June 25.

THE DYNAMO-ELECTRIC CURRENT.*

By C. TOMLINSON, D.C.L., F.R.S.

THE author, after a brief reference to the discoveries by Dr. Wollaston, Professor Oersted, of the Copenhagen, and Arago, of the Paris Academy of Sciences, on the effects of electricity on magnetic needles, on the electro-magnet, and on the subject presented, the case by Sir Charles Wheatstone, and the other by himself, to the Royal Society in February, 1827. The machine then described by him, and known in various forms as the magneto-electric, is again brought forward, the view of its construction and action being taken from the original paper. The author next adverts to the recent researches of Professor Wilde, carried out chiefly at Manchester, and which have led to the use of those machines, both of them being employed in the production of the electric light. An electro-magnetic machine is one in which the intensity of external resistance causes a falling off in the quantity of current, and in which the power of the current depends on the rate of motion, through contact between the carbon electrodes of an electric lamp, very much. Under these circumstances the excitement of the machine, and the power necessary to maintain its action, will be the rapid feeding and destructive sparks in the machine itself. An observation by Dr. Gladstone to the effect that paper is perfect conductor of electricity when dry, but a non-conductor when it is moistened, which circumstance has since been taken advantage of to some extent by Mr. Ladd and Mr. Brush, in constructing current generators.

The principal object of this paper is to establish the conditions under which magneto-electric machines may be employed, and to explain how they can be made to give maximum results. A series of tables and diagrams are given, the results of experiments conducted by Mr. Lineham, carefully, employed at the author's works, which lead up to the conclusion that, in constructing such machines on the plans principle, the resistance on the rotating coils should be equal to the resistance of the whole of the wire employed, and that on the magnets has to be increased more than twofold, not by the employment of thin wire, but by augmenting the length and weight of coil wire employed. The results of this mode of distributing the resistances is summarized as follows:—1. That the electromotive force, or power to suffer, increases with increased resistance, and that of first rapidly, and afterwards more slowly, as augmented. 2. That the current in the coils of the machine is actually greater for a coil not a half resistance than for one unit. 3. With an external resistance of one coil, which is about equivalent to an electric arc, when thirty or forty webers are passing through it, a one-horse-power is expended, of which 72*l.* horse-power is expended, of which 72*l.* horse-power is available, thus giving an efficiency of 42 per cent., as compared with 6 per cent. in the case of the ordinary dynamo-machine. 4. That the maximum energy which can be demanded from the engine is 2·6 horse-power, so that but a small margin of power is needed to suffice for the greatest possible requirement. 5. That the current intensity is about 1·6 webers, and the electromotive force about 30 volts, the latter being 1·3 horse-power, so that there is no fear here of destroying the insulation of the coils by excessive heating. 6. That the maximum current is approximately that which would be habitually used, and which the commutator and collecting brushes are quite capable of transmitting.

Generally, the author concludes that the new machine will give a steadier light than the old one, with greater average economy of power, that it will be less liable to derangement, and may be driven without variation of speed by a smaller engine; also that the new machine is free from all objection when used for the purpose of electro-deposition, the construction of machine coils and magnets being such as to render the employment of the regulator to work electric lamps, enabling him to dispense with all wheel and clockwork in the arrangement. The two carbons being pushed forward by gravity or spring power, are clocked laterally by a pointed metallic abutment, situated at such a distance from the arc itself that the heat is only sufficient to cause the volatilization of a part of the carbon in contact with atmospheric air. The arc-

*Abstract of a paper presented to the Royal Society.

bon holders are connected to the iron core of a solenoid coil, of a resistance equal to about fifty times that of the arc, the coils of which coil are connected to the two electrodes respectively. The weight of the core (which may be varied) determines the force of current that has to pass through the regulating coil, and this is the only part of the apparatus, and this is in turn is dependent upon the resistance of the arc. The result is that the length of the arc is regulated automatically, so as to maintain a uniform resistance signifying a uniform development of light. ...

VEGETATION BY ELECTRIC LIGHT.

In the State-aided Academy of Agriculture at Lagnolo, Capt. Lemuel Gulliver was introduced to a inventor who had been eighty years engaged, and expected to be so for eight years longer, in extracting azotizeous from cucumbers, which were in no put in vials hermetically sealed, and let out for horticultural purposes in raw and incitement manner. Dr. Siemens has arrived at the result which the Lagnese projecter probably missed, and in a more direct manner, by means of the electric light. At a meeting, the other day, of the Royal Society, he gave a detailed account of his experiments, which are also embodied, but the issue so far is interesting and important. He found that an electric centre of light equal to 1400 candles placed at a distance of two metres from growing plants, was apparently equal, in its effect upon the growth of plants, to the sun's illumination at the present period of the year; and that plants do not seem to require rest during the night, but when the electric light remain healthy and grow continuously, even when being at the same time fenced by artificial heat. These facts constitute additional evidence of the similarity of the electric and solar light, which is manifested in other ways. It is unlikely that the electric fluid will ever be used to supplement the solar beam on a large scale, but it is obviously possible that horticulturists who grow plants under glass may be greatly benefited by its application; and artificial waterfalls in gardens, either fed by diverting a stream, or drawn from water works, would easily supply the requisite power. The paper at the Royal Society received elegant illustration from a pot of budding tulips, which, placed in the full brightness of an electric lamp in the meeting-room, in about forty minutes unfolded into full bloom.

THE DYNAMO-ELECTRIC CURRENT AND CERTAIN MEANS TO IMPROVE ITS STEADINESS.*

BY J. Hopkinson, D.Sc., F.R.S.

The author, after briefly describing the action by Dr. Werner Siemens of the dynamo-electric or self-excitative principle of generating currents, makes reference to the two papers on the subject presented, the one by Sir Charles Wheatstone and the subject presented, the one by Sir Charles Wheatstone and the other by himself, to the Royal Society in February, 1867. The principle then designed by him was that of a governor in operation on that occasion, in again brought forward with a view of indicating the arrangement that has since taken place in the construction of dynamo-electric machines, particularly those by Gramme and Siemens-cum-Alliance. The great practical importance of the subject leads to the use of these machines, both of them being subject to the disadvantage that an increase of external resistance causes a falling off of the current; and that, on the other hand, the short circuiting of the outer terminals, through contact between the carbon electrodes of an electric lamp, very much increases the electric excitement of the machine and the power necessary to maintain its motion, giving rise to rapid heating and destructive sparks in the machine itself.

An observation in Sir Charles Wheatstone's paper is referred to, relating to the fact that a powerful current is set up in the shunt circuit of a dynamo-electric machine, which circumstance has since been taken advantage of in practice not only by Mr. Ladd and Mr. Brush, in constructing current-generators.

The principal object of the paper is to establish the conditions under which dynamo-electric machines worked on the shunt principle can be made to give maximum results. A series of curves and diagrams are given, the results of experiments conducted by Mr. Lambert, electrician, employed at the author's works, which lead up to the conclusion that, in constructing such machines on the shunt principle, the resistance of the revolving helix has to be considerably reduced by increasing the thickness of the wire employed, and that on the magnets has to be increased more than is usually done. The employment of thick wire, but by augmenting the length and weight of coil wire thick wire, but by augmenting the length and weight of coil wire and speed.

The results of this mode of distributing the resistances is summarised as follows:—

1. That the electromotive force, instead of diminishing with increased resistance, increases at first rapidly, and then more slowly towards an asymptote.

2. That the current in the outer circuit is actually greater for a unit and a half resistance than for one unit.

3. With an external resistance of one unit, which is about equivalent to an electric arc, when thirty or forty webers are passing through it, 7·14 horse-power is expended, of which 2·19 horse-power is usefully employed, proving an efficiency of 32 per cent., as compared with 45 per cent. in the case of the ordinary dynamo-machine.

4. That the maximum energy which can be demanded from the engine is 2·0 horse-power, so that but a small margin of power is needed to suffice for the greatest possible requirement.

5. That the maximum energy which can be ingeniously transferred into heat in the machine itself is 1·3 horse-power, so that there is no fear here of destroying the insulation of the helix by excessive heating.

6. That the maximum current is approximately that which would be habitually used, and which the commutator and collecting brushes are quite capable of transmitting.

Hence the author concludes that the new machine will give a steadier light than the old one with greater average economy of power, that it will be less liable to derangement, and may be driven without variation of speed by a smaller engine; also that the new machine is free from all objection when used for the purpose of electro-deposition.

This construction of machine enables the author to effect an important simplification of the regulator for the electric lamp, enabling him to dispense with all wheel and clockwork in the arrangement. The two carbons being pushed onward by gravity or spring power are elevated laterally by a pointed metallic steel bevel, actuated at such a distance from the arc itself that the latter is only just sufficient to cause the gradual wasting away of the carbon in contact with atmospheric air. The carbon holders are connected to the iron core of a solenoid coil, of a resistance equal to about 50 times that of the arc, the ends of which coil are connected to the two electrodes respectively. The weight of the core (which may be varied) determines the force of current that has to pass through the regulating coil in order to keep the weight in suspension, and this in its turn is dependent upon the resistance of the arc. The result is that the length of the arc is regulated automatically, so as to maintain a uniform resistance signifying a uniform development of light.

* Abstract of a Paper presented to the Royal Society.

ANDRÉ'S ELECTRIC LIGHT FOR MANSIONS.

While the Board of Trade is debating the question whether the electric light which is to astonish the world, and which excites the spirits of gas-shareholders and all the dingy trade, should yields them their fat dividends, and while it is directed there, then for at least a month to come, a great deal of quiet, unostentatious business and progress made in practical electric lighting, both in England and the Continent. It must be regarded as a fortunate circumstance for our inventors that they are not subjected in this country to the Italian fever. Thus, for example, the Mr. Edison, has the sweet inspiration of secret working which always ensures success and confidence—one can say he was not forced to count their chickens before they are hatched, and prematurely forth what they may or they may not be capable of doing it. The true development of an invention is seclusion, secrecy, and alone can skilful experiment be made. It is said that a rich remark is earned; while, if it fails, the worker does not incur any approbrium for unsuccessful results which would not be believed.

The electric lamp of Professor André has not been often brought before the notice of the public, yet it is a lamp on which the inventor has spent a vast deal of labour and ingenuity, and one which promises to take a high place in the electric lighting of the immediate future. It is a small lamp designed for lighting private dwelling-houses, and may be said to be in this respect unlike the ordinary lamps of Siemens, Begleff, and Jablochkoff, now to vogue, but it can also be made to give a very intense light. We recently described his first form of the lamp in *The Electrician*, page 154, Vol. III., but since then we have much improved of late by several minor improvements. It may be remembered that it is based on the incandescent principle, and consists of several pencils of carbon enclosed in an air-tight glass cylinder, which forms the globe of the lamp. The pencils are placed vertically, and their points rest on a copper electrode in the bottom of the lamp. When the current is let on these electrified points glow with great brilliance. The light lasts for many hours, because the carbons are very slowly consumed one after another in the carbonic acid gas which the air within the vessel is converted into after a few burnings. Generally speaking, M. André's lamp comes between the incandescent electric lamps of Ladigin and Shaw, which consist of a solid rod of carbon wholly heated by the passage of a current in a glass vessel filled with nitrogen gas, and the incandescent lamps of Regnier and Werdermann, which consist of incandescent carbon points burning free in air. The multiple points, the solid copper electrode for all, the carbonic acid medium, the electro-magnetic regulator, in short, the whole arrangements of the lamp are peculiar to it. Indeed it must be confessed that the idea of placing the incandescent points in an atmosphere of carbonic acid, which is so easily formed by the action of the lamp itself, and, at the same time, is so essential to protect the fine carbons from unnecessary waste, is a happy and important one, though not altogether new.

The proof of an invention lies, however, in its practice, and M. André's lamp has now earned a fair title to public consideration. An exhibition of his system of electric lighting for mansions and dwelling houses came off at Stafford House on the evening of January 26, in the presence of the Prince of Wales, the Duke and Duchess of Sutherland, Sir Frederick Leighton, and several other gentlemen. The first experiment was made with six lamps of 75 candle-power each, in circuit with 1,000 yards of cable, and fed by one small Gramme machine; the second was made with 14 lamps of 75 candle-power each, in the same circuit; the third, of 20 lamps of 50 candles each, in a circuit of 600 yards, fed by one Gramme machine; and lastly 20 lamps of 25 candles each, in the same circuit of 600 yards, and fed by the same machine. The power absorbed was from 1·2 to 1·5 horse-power per lamp.

The lantern ceiling of the grand staircase was lighted up brilliantly, clearly showing from below with very fine effect the splendid decorations overhead at a height of from 60 to 80 feet.

The dining rooms, drawing rooms, and boudoir were also lighted up with large, luminous lamps, protected by pearl, pink, and yellow tissue paper, which produced a most agreeable, soft, and steady light, and when it was required to illuminate the pictures on the walls these tissues were removed so as to throw the undiminished effulgence of the lamps upon them. His Royal Highness the Prince of Wales was, we believe, greatly pleased with the light, and Mr. André declared that it was the best display of electric lighting he had yet seen. The apparatus used at Stafford House has now been removed to the country mansion of Mr. Edward Easton, C.B., who is associated with M. André in the exhaustive development of the lamp, and will there be permanently installed on the model, to be shown the public, of André's system of domestic electric lighting. It is, we think, to be regretted that M. André should have chosen so inconvenient a place to exhibit his system, but probably he will also arrange to show it in operation in the metropolis itself.

The new lamp is not, of course, to be confined to dwelling-houses, or fiery mines, but will be found equally adapted to mills, manufactories, and other large works. The North Shore Corn Mills, near Preston, are now lighted by André's lamps, and the Liverpool Corporation, who last year obtained an Act of Parliament to light the borough of Liverpool by means of electricity, are at present considering its advantages for the purpose of lighting streets.

[The above article was crowded out of our last issue, and since then we have seen the lamp in operation, and, as usual, confess this lamp the best that has, as yet, been invented. This improvement has been made since the visit paid by the Hon R. Brougham, and will be described and illustrated next week.—*Ed. E.*]

ELECTRICITY AT TELEGRAPHY

THE SOUTH AFRICAN TELEGRAPH.—The Eastern and South African Telegraph Company announce the repair of the cable recently interrupted off Durnford Point, thus establishing telegraphic communication direct with the Cape of Good Hope.

THE INFLUENCE OF THE ELECTRIC LIGHT UPON VEGETATION.—At a recent meeting of the Royal Dublin Society Dr. C. W. Siemens, F.R.S., gave a detailed description of some experiments upon the above subject which have been conducted during the last two months at his house at Sherwood, and exhibited specimens. The method pursued was to plant quick-growing seeds and plants, such as mustard, cress, and various vegetables, in pots, and after the young plants were divided into four portions, one of which was kept entirely in the dark, one was exposed to the influences of the electric light only, one to the influence of daylight only, and one to daylight and electric light in succession. The electric light was applied for six hours each evening, from 5 to 11, and the plants were then left in total darkness during the remainder of the night. The general result was that the plants kept entirely in the dark soon died; those exposed to the electric light only or to daylight only thrave about equally; and those exposed to both day and electric light throve far better than either, the specimens of mustard and carrots exhibited to the society showing the difference in a very remarkable way. Dr. Siemens only considers himself as yet on the threshold of the investigation, but thinks the experiments already made are sufficient to justify the following conclusions:—(1) That electric light is efficient in producing chlorophyle in the leaves of plants, and in promoting growth. (2) That an electric centre of action, such as the electric light placed in close proximity to a number of young plants appears to be the most effectual means of obtaining daylight at this season of the year; but that more economical effects can be obtained by more powerful light centres. (3) That the carbonic acid and nitrogenous compounds generated in diminutive quantities in the electric arc produce no sensible deleterious effects upon plants enclosed in the same space. (4) That plants do not appear to require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected during daytime to sunlight and during the night to electric light. (5) That the radiation of heat from powerful electric arcs can be made available to counteract the effect of night frost, and is likely to promote the setting and ripening of fruit in the open air. (6) That while under the influence of electric light plants can scarcely harmed above heat without collapsing, a circumstance favourable to its forcing by electric light. (7) That the exposure of ordinary horticultural deposits mainly upon the care of exchanging carbonic acid, and the consequent production of such energy, such a supply of nitrogenous compounds as may be required for the plant, is rendered available. Dr. Siemens, in giving rise to a highly-interesting discussion, in which it was pointed out that the evidence afforded of the practical identity, as regards vegetation, of solar and electric light, besides the probability that it would be turned to immediate account by horticulturists, would afford great facilities for the scientific investigation of the influence exerted by light, as compared with other agencies, in promoting the formation of the constituents of more valuable constituents of plants, such as the quinine of the cinchona bark, the gluten of wheat and so forth. Before concluding his observations, Dr. Siemens placed a pot of budding tulips in the full brightness of an electric lamp in the meeting room, and in about forty minutes the buds had expanded into full bloom.

ABSTRACT OF PATENTS.

2301. ELECTRIC LIGHTING, &c. (*Provisional protection not left June 19th, 1879.*—*Sealed Nov. 6th, 1880.*)

The upper electrode is moved by a clamp connected to an armature-lever, which is pivoted at one end to the fixed upper piece on a fixed vertical axis. In order to diffuse the light more efficiently, an opal disc is placed under the light, and a portion of the rays pass through it, and are reflected upwards upon a bowl-reflector fixed above the electrodes.

2332. ELECTRIC LAMPS, C. D. Abel.—*Dated 11th June, 1879.*—(A communication.)—*Not proceeded with.* 2d.

The two carbon electrodes are carried by two pistons, plungers, or forms contained in two closed cylinders filled with liquid, in communication with each other, the pistons being forced by the liquid in the vessels and the weight of the pistons and arms regulating the distance carrying the carbons being so proportioned that the piston carrying the lower carbon is only lifted to descend in its vessel, causing the liquid to flow therefrom into the other vessel, and thereby raising the second piston with the lower carbon.

DYNAMO-ELECTRIC CURRENTS.

*On the Dynamo-Electric Current and on certain Conditions to Improve its Steadiness.**

By C. WILLIAM SIEMENS, D.C.L., F.R.S.

THE author, after alluding to the early conception by Dr. Wheatstone of the the dynamo-electric or reconcentrative principle of generating currents, makes reference to the independent discovery of the principle by Mr. Charles Wheatstone and Mr. Siemens, and by Mr. Varley, before the Royal Society in February, 1867. The machine then designed by him, and shown in operation on that occasion, is again brought forward with a view of indicating the progress that has since taken place in the construction of dynamo-electrical machines, particularly those by Gramme and Siemens and Halske. The latter machine has the very certain drawback in the use of time-switches, and of them being subject to the disadvantage that an increase of external resistance causes a falling off of the current; and that, on the other hand, the short circuiting of the outer resistance, through contact between the series electrodes of an electric lamp, very much increases the electric excitation of the machine, which, with a view to power economy in machine motion, causes a rapid fusing and destructive sparks in the machine itself.

An observation in Sir Charles Wheatstone's paper is referred to, pointing to the fact that a powerful current is set up in the shunt circuit of a dynamo-electric machine, which circumstance has since been taken advantage of by Messrs. Siemens, Ladd and Mr. Staite, in constructing current governors.

The principal object of this paper is to establish the conditions under which dynamo-electric machines worked on the shunt principle can be made to give maximum results. A series of tables and diagrams are given, the results of experiments conducted by Mr. Lauchert, electrician, engaged in the author's workshops, which lead to the conclusion that, in constructing machines on the shunt principle, the resistance on the retarding helix should be considerably reduced by increasing the thickness of the wire employed, and that on the magnets less to be increased more than tenfold, not by the employment of thin wire, but by augmenting the length and weight of coil wire employed.

The results of the method of distributing the resistance, is enumerated as follows:

1. That the electro-motive force, instead of diminishing with increased resistance, increases at first rapidly, and then more slowly towards an asymptote.

2. That the current in the outer circuit is naturally greater for a small than for a large resistance.

3. With an external resistance of one unit, which is about equivalent to an electric arc, through which the currents are passing through it, 1.61 horse power is developed, of which 1.25 horse power is usefully employed, giving an efficiency of 50 per cent., as compared with 45 per cent. in the case of the ordinary dynamo-machine.

4. That the maximum energy which can be demanded from the engine is 2.6 horse power, so that but a small margin of power is needed to suffice for the greatest possible requirements.

5. That the maximum energy which can be injuriously transferred into heat in the machine itself is 1.2 horse-power, so that there is no fear here of destroying the insulation of the coils by excessive heating.

6. That the maximum current is approximately that which would be indicated by a tangent drawn to the curve below and coinciding therein with the axis of transmitting.

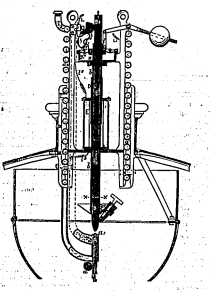
From the author concludes that the new machine will give a steadier light than the old one with greater average economy of power; that it will be less liable to derangement, and may be driven without variation of speed by a smaller engine; also that it will be free from all the objection when used for the purpose of electro deposition.

* Abstract of paper read before the Royal Society, March 4, 1880.

This consideration of machine enables the author to effect an important simplification of the regulation of the electric current, making him to dispense with all electric time-clockwork in the arrangement. The two carbons in the lamp are caused by a helical metallic retaining spring are allowed laterally from the arc itself, that is, at a point of only just sufficient to cause the gradual wasting away of the carbon in contact with atmospheric air. The carbon holder is then connected about fifty times that of the arc, the ends of the coil are connected to the two carbon holders respectively. The force of current that has to pass through the regulating coil in order to keep the weight in equipoise, and this is therefore dependent upon the resistance of the arc. The resistance, and that length of the arc is regulated automatically, so as to maintain a uniform resistance signifying uniform development of light.

SIEMENS' SINGLE CARBON ELECTRIC LAMP.

THE construction of this lamp, to which we referred in our last issue,* is as follows:—In the fig., which represents a vertical section of the lamp, A is the lower electrode, formed of an iron or steel wire loosely fitting in a water-cased tube, and pressed upwards by a volute spring, *s*, or by a weight and pulley. The mouth of the water-cased tube has a bush, *s*', closely fitting the wire A, or having a burr at its mouth, so as to prevent the wire from being pushed through it, except when its point becomes softened, fused, and dissipated by the heat of the voltaic arc. The water circulating through the casing of the electrode may flow to and from an open cistern, or it may, as shown in fig. 1, circulate through a closed coil of tube, *s*', presenting a considerable cooling surface. The upper electrode, B, is a carbon rod free to slide in a tube, *b*, having two carbon slits at the lower end of the tube, B, is provided an oblique adjusting screw, C, the point of which bears against the carbon and presses it against the ribs on the opposite side of the tube, so that being in a manner clamped between these ribs and the screw, C, it cannot slide down. Moreover, from the pressure of the carbon against the ribs, *b*, close contact results, so that the electricity enters the carbon at its point of contact with the ribs, and consequently the heating of the carbon is confined nearly to the portion of it which projects below the tube. As the lower end of the carbon gradually wastes away from the point, C, the carbon gradually slides down the tube. The screw, C, may be of copper, as a good conducting material, or its point may be of refractory metal, such as platinum, or it may be a refractory gem, such as diamond, let into the point of the screw, C, which is guarded from the heat of the arc by a shield of porcelain or refractory metal. The screw, C, works in a shield, *c*', of convex or inverted conical form enamelled or faced with porcelain on its lower surface, so as to reflect the light as well as to protect the tube, *b*, from the heat of the arc. As the carbon, B, becomes consumed and descends, the carbon, *b*, a fresh carbon, B', can be added to it; for this purpose the upper end of the new carbon is hollowed out a little, and the lower end of the fresh carbon is served with a little moistened sugar, or with tar, which, as the junction approaches the lower end of the tube, becomes carbonized by the heat, cementing the two carbons together. It is of advantage to provide in each carbon a short piece of wire, *b*', to act as a dowel, centering the carbons to one another; or the one carbon might be made with a point projecting as a tenon to enter a hole in the end of the other carbon. The automatic adjustment of the distance of the electrodes is effected in the following manner:—



SIEMENS' SINGLE CARBON ELECTRIC LAMP.

The tube, *b*, has on it, a cylindrical casing, *b*, of soft iron; or instead of a complete cylindrical casing, the iron may be put on the tube as a number of strips arranged round its circumference. Around the tube, *b*, is the coil of a solenoid, *a*, consisting of a great number of convolutions of insulated wire, so as to present very considerable electrical resistance. This solenoid coil forms part of a circuit connecting the one terminal with the other, as will be understood by tracing the course of the electrical current from the one line wire, L, to the other line wire, L'. The one wire, L, is attached to an insulated connecting piece, *f*, from which a flexible metallic strip, *f*', connects to the tube, *b*, holding the upper carbon, and a wire, *f*', connects to the solenoid coil, *a*, the other wire, L', is connected directly to the frame of the lamp, which is all in metallic connection with the lower terminals, and also by a wire, *f*', with the solenoid coil, *a*. The tube, *b*, and its carbon being a little more than counterbalanced by an adjustable weight on a lever connected to the tube by a non-conducting link, *f*, the regulation of the distance of the terminals depends upon the

A NEW YORK correspondent of the *Standard* says:—That of the 200 paper carbon lamps tried by Mr. Edison, only two remain at present undestroyed. A professor of Harvard University has sent him 50 specimens of discs to test for the carbon horse-shoes instead of the paper formerly used. Mr. Edison finds manilla is the best of them for his purpose." Amongst those who have the best opportunity of judging what he has done, or is likely to do, little hope seems to remain of his ultimately attaining success with his incandescent lamps.

EDISON'S NEW DISCOVERY.

New York Graphic Journal, Dec. 2, 1880

We clip from the N. Y. *Evening Post* the following account of a:—

"A gentleman who visited Menlo Park last week on behalf of the Boston *Journal* reports that all except two or three of the paper carbon lamps have been taken down, and that Edison admitted that they had been destroyed."

It would hardly seem credible that the above can be exact; but if it is there is much consolation in the fact that something substantial looms up in the future, if the following from the N. Y. *Times* is true:

"In the intervals of his wrestle with the electric light, Mr. Edison finds time to chip off numerous minor inventions, any one of which should be sufficient to revolutionize the world, if the world knew what was good for it. Mr. Edison's latest discovery is a method by which, it is announced, "to can extract a greater amount of gold from the rejected residuum or 'tailings' of auriferous quartz or sand than is obtained by the present processes from the virgin rocks." In other words, after the ore, crushed and triturated in the usual manner, has yielded its average of 20 to 40 dollars a ton, Mr. Edison takes the refuse and extracts from it—at the merely nominal cost of five dollars—all the way from $80 to $250, or even $1,400 a ton. It is well remarked by the New York *Herald*, from which the account of this wonderful discovery is derived, that "the wealth which is likely to result is beyond computation." Mr. Edison would seem, indeed, to have realized the dream of the alchemists and to have found the philosopher's stone. It is perhaps unnecessary to add that "before allowing his discovery to be known beyond the small circle of his confidential associates," the "Edison Ore Milling Company" was formed, "Mr. Edison himself holding a place in the Board of Directors." The confidential associates have not yet placed their stock upon the market, but it is probable that a few shares may shortly be purchased, at an advance, if any reader of the *Times* desires to go in."

THE LONTIN ELECTRIC LIGHT.

IT has long been acknowledged by electricians that for brilliancy and reliability the Serrin lamp left little to be desired, and it seems that this little has now been supplied in the Lontin, which is one step forward in the development of the same system. A number of scientific gentlemen and electricians lately met at the Three Nuns Hotel, adjoining the Metropolitan Railway, Aldgate, London, to see, previously to examining the light in use on that line, an account of the progress in perfecting the Lontin apparatus. The Lontin light has for some time past been and still is in successful use in Paris, and is not unknown to the inhabitants of and visitors to London, being that which was for some time exhibited in the Strand during last winter by Mr. John Hedlingsteel, of the Gayety Theater. Since that time, many little imperfections were noticed by those interested have been remedied, and eight lamps are now in use at the Aldersgate-street Station of the Metropolitan Railway. At the meeting in question, the chair was occupied by Mr. Alan Fenton, the general manager of that line, and Mr. C. F. Harding, who first introduced the light in this country, and in whose workshops all the machinery at present constructed, having explained the details of the improvements recently made, and been introduced since the system was first brought before the public, there was an interesting discussion, in which Mr. W. Conran, F.R.S., Mr. Tomlinson, the engineer of the Metropolitan Railway, and others took part. The opinion was without exception favorable to the quality and efficiency of the Lontin lamp, but some fear was expressed that the present high price would probably limit its application.

The economy of the system was ably maintained by Mr. Bernard Godfrey, the engineer of the Lontin Light Electric Generator and Light Company, who, by the aid of samples of the various forms of the lamp, showed very clearly the progress made up to the present time. He explained that the first cost of the lamp was really less than that which at first sight appeared, owing to the small number of electric lamps required for a given space and their durability, but to meet this popular objection efforts were still being made, and he hoped before long they would have a lamp in which the clockwork was entirely dispensed with, the result of which would be that even in first cost the Lontin would compare favorably with any lamp known. It is but nine months since the first practical application of the electric light for public illumination was initiated in London with the Lontin system at the Gaiety Theater, and it has already in spite of the indisposition of over sanguine projectors and the detraction of opponents, become admittedly a method of lighting which public bodies have to reckon with, being alone adopted on the score of power, salubrity, cleanliness, and economy, under its present improved and improving conditions, to satisfy certain large special requirements. It is to meet these special wants that the above company has acquired the only complete system of lighting which now exists. In fact, without in any way depreciating the brilliant results obtained by other inventions, it may be fairly stated that, whilst one company deals with a machine of which the subdivision is limited, and another company with the utilization of a burner or candle, each having its special feature and being dependent on others for the rest, this company holds not only the Lontin generator, but also the regulators, lamps, and methods of subdivision which enable it to supply from its own resources a complete and practical system of lighting which is neither disagreeable in color nor unsteady in light.

It was claimed for the Lontin light that it has decided advantages over the circle in steadiness, in divisibility, and in economy, the cost of the Lontin being as compared with 9.3d. for the next cheapest light. The illumination of the Aldersgate street Station on Monday was very brilliant in every part, although but eight lamps were used to light the whole of the platforms. The lamps were on four circuits, and the currents were supplied from a Lontin generator producing alternate currents and making only 400 revolutions per minute. The motive power was obtained from a Fowler's semi-portable compound engine, high pressure cylinder 9 in. diameter, and low pressure 16 in. diameter, with about a 14-in. stroke. The steam was used at 112 lb. pressure on the square inch, and the engine was making about 109 revolutions per minute. From these data practical men can calculate approximately the number of indicated horse power used. It is intended with the same machinery to illuminate the Moorgate-street and Farringdon stations also, which will be a severe and conclusive test of the efficiency of the system. It is stated that the light may be divided very greatly. As many as two or three lights have been placed in one circuit. It has been shown practically that by this machine it is possible to give a larger number of small lights; and so far as experience has hitherto gone, whatever loss there may be in illuminating power is much more than counterbalanced by the convenience of so complete a distribution; however, curiously enough, up to a point which at present appears to be between four and six lights on a circuit, a positive gain is obtained by division. These experiments are not yet completed. A machine constructed nominally for twelve lights (which would mean twelve lights of 600 candle-power each), may be arranged to produce 48 lights, should the nature of the application make such division desirable. The various patents which are the property of this company include special regulators and lamps, as well as special materials for cables and insulation, so that the whole apparatus necessary for the purposes of electric lighting used in this system is to a great extent peculiar to itself, and constructed under its own direction and control. The experiments on Monday evening were in every respect satisfactory, and promise much for the future of the light.

THE SAWYER ELECTRIC LIGHT.

The practical working of the Sawyer system of electric lighting was recently exhibited in a few gentlemen's ordinary, uptown residence on West 34th street, in this city. Seven lamps were distributed at convenient points—three in the rear of the hall, one upon the center-table, a sixth in the front parlor, and seven in the front parlor, two upon a double arm gas fixture and five upon ordinary pattern in the front parlor, and three in the back. It is stated that the seven lamps are operated upon one

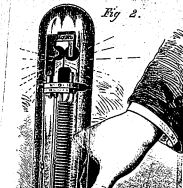


Fig. 2.

AMERICAN INDUSTRIES, No. 38.

THE MANUFACTURE OF PRINTING INKS.

On the first page of this paper we illustrate the leading processes of the printing ink manufacture, as conducted by one of the oldest houses in that branch of business. In the early history of printing it was common for printers to make their own inks; but with the more varied requirements of modern printing offices, it has been found that greater economy and generally better results could be obtained by making of this department a separate trade.

The making of first-quality printing inks is a nice operation; it requires a high degree of skill and a variety of judgment obtained only by long experience, although the general methods employed have shown but little change in many years. All practical manufacturers have, however, certain trade secrets, the value of which would be recognized only by an expert, but which they carefully guard, tending the details of grinding the color, making the varnish and lampblack, and the various pigments they employ in colored inks.

In our illustrations the view at the upper right hand corner shows the furnaces in which the lampblack is made. This is the color basis of most of the black inks, although finely divided charcoal and occasionally other blacks are also used to some extent. The making of the black is a simple and well understood process, but on the materials employed therefor and the quantity of black used depends much of the success of the ink manufacturer.

The picture to the left at the top, showing the varnish making, presents a part of the business on which, quite as much as the color, depend the distinctness and brilliancy of all fine class inks. Linseed oil is largely used for this purpose, though other oils are likewise employed, and resin oil has been extensively used in the cheaper inks. By boiling the fatty constituents of the oil—glycerine, palmitine, etc.—are volatilized. For the best inks, the oil is clarified by digesting for some hours with dilute sulphuric acid at a temperature of 212 degrees, then washing with hot water, when it will dry quickly and thoroughly; the oil is then boiled, and the inflammable vapors that rise are ignited, which, after burning for some time, are extinguished by a cover placed over the vessel. In order to promote quick drying, manganese in its different states and other driers are sometimes added. The view entitled "color plant" shows the department where the various pigments for colored inks are prepared. These are made of almost everything which can be practically worked to give the different shades desired, either mineral, animal, or vegetable, the pigments being prepared so as to be as little liable to change as possible, and then kept on hand to make the basis of the different colors, by taking exact quantities or proportions by weight of each. The cost tar or asphalt colors have been very fashionable for some years, and, although they give great brilliancy at first, it has been found they are not lasting.

The black ink making room at the right of the general view shows where the lampblack or other carbonaceous blacks employed are mixed with the varnish in the barrel and rosin. The mixing is effected in a cylindrical vessel by a revolving shaft with fingers.

The color grinding, as shown in the large view at the bottom of the page, is done by powerful iron or stone mills, in which rollers of great strength, driven by steam power, reduce the mixture to so fine a state that no coarse particles can possibly pass.

Besides the ingredients mentioned above, soap is sometimes used in order to prevent smearing, assist in obtaining sharpness of impression, and help to make the ink have the proper

perties this light is much like gas. It is yellow, steady, and soft," and consequently not irritating, to the eye. It has none of the blue rays incident to the voltaic arc arrangement, and the shadow cast by intervening objects is softened and mellowed at the margin. For practical purposes it is intended that the power of each lamp shall not exceed that of two ordinary gas jets.

The relative economy of this system of lighting we are unable to learn. "Approximate estimates" of cost make it much cheaper than gas; but in the absence of specific data for exact calculation, such estimates do not go far to satisfy the popular mind.

ELECTRICITY.

The Standard Nut Works, of Pittsburgh, Pa., has adopted the Brush electric light.

An organization to be known as the New York Land Telegraph Company has been started, for the purpose of laying another cable across the Atlantic.

The Common Council of Boston will probably pass an ordinance regulating the erection of telephone and telegraph wires to prevent interference with the Fire Alarm Telegraph.

It is stated that the Gulf Submarine Cable Company will commence laying the cable during the latter part of this month, starting at Bermuda Santiago, thence to Vera Cruz or Tampico.

THE EDISON ELECTRIC LIGHT.

The following extracts from Professor BARKER'S paper in Silliman's *American Journal of Science* for April, 1880, as from the pen of Professor MARSH, a colleague of Professor BARKER in the University of Pennsylvania, and a gentleman of distinguished professional standing:

EDITOR ENGINEERING AND MINING JOURNAL.

SIR: The recently published results of the experiments of Professors Rowland and Barker are the only reliable data with regard to the Edison light which have as yet been presented to the public; and while these results are undoubtedly mathematically correct, save the assumption, *wholly unwarranted by any quoted experiments*, that the power which reaches the lamp is to the power developed by the engine as 70 is to 100, they convey to the general reader a wrong impression of the practical working of the light as it now is.

The professors have apparently overlooked the fact that distribution of light, rather than production of light by means of electricity, is the end which must be attained by Mr. Edison before his light can be deemed a practical success.

The economy of the production of light by electricity will be found to be greatly increased as the intensity of the light produced at any one point is increased; and the experiments made show that, with a light suitable to replace an ordinary gas-jet, and without making any allowance whatever for losses in the engine, electric machine, or wires, about 754 five-foot gas-jets can be replaced by one horse-power in the form of electricity.

Taking Professor Rowland's assumption of 70 per cent of the electric light per horse-power in electricity is equal to the light per indicated horse-power at the engine, we have 754 lights per indicated horse-power. The writer is inclined to believe that about 5 lights per horse-power per hour is in excess of what Mr. Edison is now doing, as he is informed by Edison's engineer that the engine, when developing about 90 horse-power, ran about 90 lights, which, burned very much in the same manner as a similar number of gas-jets. We see that each horse-power corresponds to about 4 6 lights of the apparent brilliancy of ordinary gas-jets, which hardly ever consume as much as 5 feet of gas per hour.

The average cost of one horse-power per hour, when fuel, attendance, lubrication, and wear and tear on belts, shafting, etc., are counted in, is about 4 cents per hour. This cost is the actual result in some of the best works about Philadelphia.

The comparative cost of electricity and gas can now be computed:

	Per 1000.
For 754 lights per horse-power per hour, illuminating-gas costs	$1.00
" " " " " " "	1.00
" " " " " " "	1.00

The method of computation is very simple: 754 lights, if replaced by gas, would require 754 × 5 cubic feet of gas = 3770 cubic feet. Then we have, by the rule of three,

$$3774 : 1000 :: 4 : 107.$$

In admitting that Edison has produced 754 *separate* lights of say 17 candle-power per indicated horse-power, we give him better results than he himself can claim.

Now, it is easy to see that if the gas companies are producing gas and getting it into the holder for less than the present figures given ($1.00), it will be impossible to supersede gas by electricity until further advances have been made in the reduction of its cost, allowing that the electric plant will cost no more than the plant of an ordinary illuminating-gas company.

All those familiar with the manufacture of gas know that it is produced at a cost far below $1.07 per thousand.

The writer has no desire to depreciate Mr. Edison's work, and heartily wishes him a rapid and successful result from his labors; but it is wrong as well as unjust to endeavor to create a sensation by misconstruing the results of Professor Rowland's measurements, and by dabbling in statements as to comparative cost of electricity and illuminating-gas without actually knowing either.

WILLIAM D. MARSH,
Prof. Dyn. Eng.

UNIVERSITY OF PENNSYLVANIA, April 18.

Edison's Latest.—*The Herald* is authority for the statement that Mr. Edison has found them in the intervals of his work on the electric light to make a remarkable discovery in another field. The industry which Mr. Edison proposes to revolutionize is the metallurgy of the precious metals. The *Herald* informs us that Mr. Edison has discovered a means whereby which "he can extract a greater amount of gold from the refractile portions of tailings" of auriferous quartz and ores heretofore left by the present processes from the virgin rocks." To state it differently, Mr. Edison proposes, according to this account, after the ore has been treated by the usual processes of milling and amalgamating, and has yielded as from 75 to 95 per cent of its gold, according to the ores with which it has been worked, to take the refuse and extract from it at merely nominal cost—anywhere from $50 to $1000 per ton. Mr. Edison may probably have discovered the philosopher's stone by which to transmute baser substances into gold; but on any other supposition the statements made by the *Herald* reporter are too ridiculously canvagant to merit serious consideration. It is by permitting unobtrusive newspaper men to scatter such statements as the above broadcast without demur in examining from him, that Mr. Edison is, to say the least, not adding to his reputation.

Dr. C. Stenzera has reached some curious conclusions respecting the influence of the electric light upon vegetation. He finds that the growth of plants is considerably promoted when they are continuously exposed to the ultimate action of sunlight and the electric light. This, he holds, proves that plants do not require rest, but that growth can be materially hastened by giving them a portion of the electric light at night, and that the electric light will produce chlorophyll in the leaves of plants, and promote their growth. In lecturing on this subject, Dr. Siemens illustrated his subject by placing some budding tulips in a strong electric light, which, in about 40 minutes, caused the buds to open out in full bloom.

A New Process for Etching on Copper.—From the London *Photographic News* we glean the following particulars of a new procedure for etching on copper, which has the merit of simplicity. A copper plate is first coated with bitumen on the turning-table, in the same manner as for "photo-zincography." When the coating is quite dry, an impression from a lithographic stone on transfer-paper is applied to it, which leaves behind a greasy and fatty impression of the design. The plate is then dusted with ebb's powdered powder, which adheres only on the inked portions, rendering them very opaque. The plate is now exposed to the light, which renders the portions of the bitumen coating not covered by the powder insoluble. Then a solvent for bitumen is applied, which removes the bitumen beneath the powdered parts, laying bare the copper surface in those parts corresponding to the picture. The copper plate can now be etched with perchloride of iron or other etching liquid, and when sufficient depth has been reached, the operation can be stopped and the whole plate cleaned. The process is said to be well adopted for line work.

ON THE INFLUENCE OF ELECTRIC LIGHT UPON VEGETATION—AND—ON CERTAIN PHYSICAL PROPERTIES OF OZONE.*

The vast importance of vegetation to animal life in association in accordance with the well known fact that plants exhale oxygen, which both flower and carbonic acid are broken up in order that, conversely, plants may exhale oxygen for animals. It is well known that this reaction depends upon solar radiation; but the question now arises, Do the blood-rays of the spectrum, or that agency, or whether other sources of light and heat which are rich in them, as the electric light, possess the character of illuminating rays and the heat-radiation in order to continue the action of growth, when the true solar rays are not or is hidden behind clouds?

About two years ago I mentioned to Sir Joseph Hooker, then President of the Royal Society, that I thought the electric arc might be found sufficiently powerful to promote vegetation, and that I should be willing to undertake some experiments on the subject if he could give me any hope of confirmative results. Sir Joseph Hooker gave me sufficient encouragement to induce me so follow up the subject, and I have since then gradually matured a plan for conducting the experiment.

The apparatus which has been put up at Sherwood consists—1. Of a vertical Siemens dynamo-machine, weighing 50 kilos, with a wire resistance of 2 ohms on the electromagnets. This machine makes 1,000 revolutions a minute; it takes 3 horse-power to drive it, and develops a current of 35 to 37 webers of an intensity of 70 volts. 2. A regulator lamp constructed for continuous currents, with two carbon electrodes of 12 millims. and 10 millims. diameter respectively. The light produced is equal to 1,500 candles measured photometrically. 3. A motor, which at present is a 3 horse-power Otto gas-engine, but which it is intended to supersede by a turbine to be worked by a natural supply of water, at a distance of about half a mile from the house.

My object in making these experiments was to ascertain whether electric light could be decided effect upon the growth of plants. For this purpose I placed the regulator in a lamp-shade in a conservatory, which, although the interior of the experiments is too limited perhaps to furnish that proof in an absolute manner. I may, however, be argued from analogy that such repose is not necessary, seeing that crops grow and ripen in a wonderfully short space of time in the northern regions of Sweden and Norway and Finland, where the summer does not exceed two months, during which period the sun scarcely sets.

The next step in the course of these experiments was to remove the electric lamp from the glass house known constructed of framed glass, 9 ft. 3 in. long, 14 ft. 3 in. wide, framed glass, 9 ft. 3 in. long, 14 ft. 3 in. wide, and averaging 8 ft. 6 in. in height, and to place it in a detached glass house a house a house and a few other small trees are planted, the sides of the house all round being occupied with a considerable variety of flowering plants. The electric light was fixed as high as practicable at the south corner of the house in order that its rays might fall upon the plants from a direction and at an angle coincident with those of the sun during the middle of the day. The temperature of the house was maintained at 60° F., and the electric lamp was kept alight from 2 P.M. to 6 A.M., for one week, from February 19 to February 24, excepting Sunday night. The time was hardly sufficient to produce very striking effects, but all the plants continued in present a healthy appearance.

Of three Alicante vines the one nearest the electric light made most progress; and the same could be said of the nasturtiums and roses. It was observed that other plants, such as geraniums, continued to exhibit a vigorous appearance notwithstanding the heat of the plant. This experiment is of importance in showing that the electric light, if put into conservatories or greenhouses, does not injure the plants but rather improves their appearance and growth. The leaves assume a darker and more vigorous appearance, and it seems that the coloring of the flowers becomes more vivid; but a further period of time is necessary to establish this observation absolutely.

I decided to try the effect of electric light as a means of promoting growth in the open air and under glass at the same time.

The regulator was put back into its first position, two meters above the ground, with a sunken melon house on one side, and a sunken house containing roses, lilies, strawberries, and a variety of other plants on the other. The space of ground between these, about one meter broad and seven meters long, was covered with boxes sown with early vegetables, including mustard, peas, beans, and potatoes; and in order to prevent cold winds from injuring the plants, low protecting screens were put up across the openings of the passage between the two houses.

These experiments were continued during four days and nights consecutively, and the results observed are of a very striking and decisive character as regards the behavior of small flock-growing plants as mustard, cress, etc. The plants that had been exposed to day-light alone (comprising a fair proportion of sunlight) presented their usually healthy green appearance; those exposed to electric light alone were, in most instances, of a somewhat lighter, but in one instance of a somewhat darker hue than those exposed to daylight; and all the plants that had the double benefit of day and electric light far surpassed the others in darkness of green and vigorous appearance generally. A pot of tulip bulbs was placed in this electric stove, and the flowers were observed to expand somewhat after two days.

Although the access of stove heat was virtually stopped, the temperature of the house remained constant throughout the night at 72° F., so that the electric lamp furnished not only a supply of effective light, but also of heat. No injurious effects were observed on the plants from the want of ventilation; and it would appear that the supply of pure carbonic acid resulting from the continuous combustion of the carbonic electrodes of high temperature, and under the influence of an open flame, suffices to assimilate their vital functions. If the nitrogenous compounds which Prof. Dare has shown to be developed in the electric are were produced in large quantities, injurious effects upon the plants must undoubtedly ensue; but in no case have I

* Abstract of a paper read at the Royal Society on March 4, by C. Wilhelm Siemens, D.C.L., F.R.S.

1 Prof. Stokes has shown, in 1857, that the electric arc is particularly rich in highly refrangible invisible rays, a circumstance which seems to point to a great loss of heating them rays through glass.

in a well-conditioned electric lamp, with a free circulation of air round the carbon electrodes, the amount of these products is exceedingly small and of a different nature than is produced in a confined space.

These experiments are not only instructive in proving the sufficiency of electric light alone to promote vegetation, but they also go to prove the important fact that diurnal repose is not necessary for the life of plants, although the duration of the experiments is too limited perhaps to furnish that proof in an absolute manner. It may, however, be argued from analogy that such repose is not necessary, seeing that crops grow and ripen in a wonderfully short space of time in the northern regions of Sweden and Norway and Finland, where the summer does not exceed two months, during which period the sun scarcely sets.

The next step in the course of these experiments was to remove the electric lamp from the glass house known constructed of framed glass, 9 ft. 3 in. long, 14 ft. 3 in. wide, framed glass, 9 ft. 3 in. long, 14 ft. 3 in. wide, and averaging 8 ft. 6 in. in height, and to place it in a detached glass house a house a house and a few other small trees are planted, the sides of the house all round being occupied with a considerable variety of flowering plants. The electric light was fixed as high as practicable at the south corner of the house in order that its rays might fall upon the plants from a direction and at an angle coincident with those of the sun during the middle of the day. The temperature of the house was maintained at 60° F., and the electric lamp was kept alight from 2 P.M. to 6 A.M., for one week, from February 19 to February 24, excepting Sunday night. The time was hardly sufficient to produce very striking effects, but all the plants continued to present a healthy appearance.

Of three Alicante vines the one nearest the electric light made most progress; and the same could be said of the nasturtiums and roses. It was observed that other plants, such as geraniums, continued to exhibit a vigorous appearance notwithstanding the heat of the plant. This experiment is of importance in showing that the electric light, if put into conservatories or greenhouses, does not injure the plants but rather improves their appearance and growth. The leaves assume a darker and more vigorous appearance, and it seems that the coloring of the flowers becomes more vivid; but a further period of time is necessary to establish this observation absolutely.

I decided to try the effect of electric light as a means of promoting growth in the open air and under glass at the same time.

The regulator was put back into its first position, two meters above the ground, with a sunken melon house on one side, and a sunken house containing roses, lilies, strawberries, and a variety of other plants on the other. The space of ground between these, about one meter broad and seven meters long, was covered with boxes sown with early vegetables, including mustard, peas, beans, and potatoes; and in order to prevent cold winds from injuring the plants, low protecting screens were put up across the openings of the passage between the two houses.

Some weeks must elapse before any definite results can be given, but growth is evidently promoted under all these various circumstances. In order to test this clearly, a portion of the plants both under glass and in the open air are shaded from the electric light without removing them from their position of equal temperature, and exposed to solar light at the same time as before. The effect upon the flowering plants is very striking, electric light having apparently more efficacy to bring them on than daylight.

Although the amount of heat given off from the electric arc is not great, compared with the gas flame (giving off the products of combustion), yet the rays of intense heat of the arc are counteract that loss of heat by radiation from the leaves into space, which, during a clear night, causes hoar frost. For this reason I expect that electric light may be usefully employed in front of fruit walls, in orchards, and in kitchen gardens, to save the fruit bud at the time of setting; and in this application electric light will probably be found a useful agent not only to promote rapid growth, but to insure a better yield of fruit.

The experiments seem to lead to the following conclusions:

1. That electric light is efficacious in producing chlorophyl in the leaves of plants and in promoting growth.

2. That an electric center of light equal to 1,400 candles, placed at a distance of two meters from growing plants, appeared to be equal in effect to average daylight in the season of the year, but that more economical effects can be attained by more powerful light centers.

3. That the carbonic acid and nitrogenous compounds generated in diminutive quantities in the electric arc produce no sensible deleterious effects upon plants inclosed in the same space.

4. That plants do not appear to require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected during daytime to sunlight, and during the night to electric light.

5. That the radiation of heat from powerful electric arcs can be made available to counteract the effect of night frost, and is likely to promote the setting and ripening of fruit in the open air.

6. That while under the influence of electric light plants can sustain increased stores both without collapsing, a circumstance favorable to forcing by electric light.

7. That the expense of electro-horticulture depends mainly upon the cost of mechanical energy, and is very moderate where natural forces of such energy, such as waterfalls, can be made available.

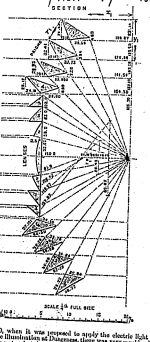
Since writing the above my attention has been drawn to an article in *Nature*, vol. xxi., p. 311, giving interesting observations by Dr. Schübler, of Christiania, on "The Effect of Uninterrupted Sunlight on Plants in the Arctic Regions." These observations fully confirm the conclusion indicated by my experiments with electric light. Not only are plants able to grow continuously, according to Dr. Schübler, but when under the influence of continuous light, they develop more brilliant flowers and larger and more aromatic fruit than under the alternating influence of light and darkness, whereas the formation of sugar appears to be dependent chiefly upon temperature.

It would follow from these observations that, with the aid of stoves and electric light, fruit, exciting both in sweetness and aroma, and flowers of great brightness, may be grown without solar aid. Dr. Schübler mentions that, in removing an arctic plant from the dark and placing it under the influence of the Arctic midnight sun, the leaves opened slowly, and it is interesting to observe that the same effect took place when an *Aesculus hyppocastanum* was placed (in the open air) under the influence of my midnight lamp.

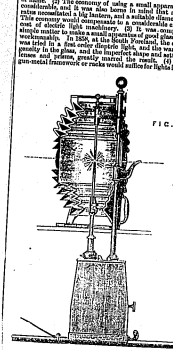
DIOPTRIC APPARATUS IN LIGHTHOUSES FOR THE ELECTRIC LIGHT.

SIR,—I have recently read a paper on this subject by Mr. James Chance, published in volume 57, 1876-77, part 2, of "Minutes of Proceedings of the Institution of Civil Engineers." Absence from England when it was read and discussed prevented me from attending the meeting, or I otherwise should have done so. I would ask you to be kind enough to insert in your valuable journal the following remarks, which I feel may will be of interest to several of your readers.

Engineer April 1880



In 1850, when it was proposed to apply the electric light to lighthouse illumination and purposes, there was very considerable discussion as to what class of dioptric apparatus should be employed. It was finally decided to adopt the zone order, for the following reasons:—(1) The size of the luminous point, which, it was considered advisable to have a distinctive optical character, to enable the nautical amount of divergence might be obtained. Previously, the order of apparatus had been proportioned to the size of flame. (2) The economy of using a small apparatus would be considerable, and it was also known that a small flame gave a more concentrated light, and a smaller diameter of lenses. This economy would compensate to a considerable extent for the simpler matter to make a small apparatus of good glass and good workmanship. In 1849, at the South Foreland, the electric light was tried by Mr. Faraday, the electric light, and the want of homogeneity in the glass, and imperfect shape and setting of both lenses and prisms, greatly marred the result. (4) Very thin gun-metal frames were or rules would suffice for lights illuminating

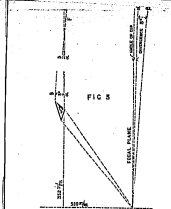


the whole horizon, and in those illuminating only a portion of the horizon—which is the more common—it was practicable to use only one very thin rack, that might be fixed, or might be divided into two parts not coming in the same vertical plane, so that the shadow would be obstructed. A modern catoptric construction would also little light. Thus a practically uniform light could be obtained.

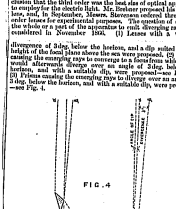
The two first apparatuses for the electric light used at Dungeness illuminated 252° 0m., and were of the fifth order, with one fifth inclined holophotal rack to each. The effect was far from perfect, and the glass changed colour very considerably. The apparatus first used, as shown indicated in Fig. 3, was constructed entirely to replace those temporarily in use. In the refracting drum, as inclined to the horizontal, with the direction of the refracted ray, was used in the 2nd, 3 and 4th orders.

This soon year the Trinity House authorities established a sixth order light at Cape la Hève, as shown in Fig. 2; and in further information, see "Minutes of Proceedings of the Institution of Civil Engineers," by M. Léonce Reynaud.

A zone dioptric apparatus for the electric light was exhibited in the machinery annexe in the 1862 Exhibition. The effect of the electric light in the focus of an annular lens of the third order, if I remember correctly, was also exhibited.



In 1862 Messrs. D. and T. Stevenson, of Edinburgh, proposed the adoption of a tilted order apparatus for the electric light. (3) "Lighthouse Illumination," by Thomas Stevenson, second edition, will contain the interesting chapter on the electric light, and in it some of the experiments made with the apparatus are very refined, such. In July, 1862, Messrs. Chance, Brothers and Co. submitted designs and specifications to the Trinity House for electric lights for the high and low South Foreland Lighthouses. The epitied portion of the specification was drafted by Mr. James Chance, whilst the mechanical portion of the apparatus, and the directions were left to myself. All the fittings, lights, and apparatus were to be complete. It was my conviction that the tilted order was the best size of optical apparatus to employ for the electric light. Mr. Brebner proposed his laws of lens, and, in September, Messrs. Stevenson ordered three tilted order lenses for experimental purposes. The question of causing the whole or part of the apparatus a small diverging rays was considered in November 1863. (1) Lenses with a vertical



divergence of 2deg, below the horizon, and a dip added to the height of the focal plane, so that the sea was very pressed. (2) Prisms causing the sweeping rays to converge to a focus from which they would afterwards diverge over the sea, as in the case of (1) above the horizon, and with a suitable dip, were proposed—see Fig. 4. (3) Prisms causing the sweeping rays to diverge over an angle of 2deg. below the horizon, and with a suitable dip, were proposed —see Fig. 4.

It was however finally decided by Mr. James Chance that the tilted order should be used, which was afterwards exhibited in Paris in 1867, should have (1) its lenses and prisms calculated for the emission of parallel rays of light. Mr. Chance's opinion at that time was, that however accurate practically the refractor might be worked, there was sure to be sufficient

divergence of convergence. The result, quoted Mr. Chadwick ridiculous incorrect, and in the Senior Nicol electric light, designed by him in 1876, a portion of the refractor emitted diverging rays. A divergence of 3 deg. below the horizon, and of 10 deg. above was adopted. The result was a maximum divergence of 7 deg. was adopted. The result was a maximum divergence of 7 deg. was adopted. The result was a maximum divergence of 7 deg.

VEGETATION UNDER THE ELECTRIC LIGHT.

At a recent meeting of the Royal Society, London, Dr. Siemens gave a detailed description of some experiments in connection with the subject which had been conducted during the last two months at his house at Sherwood, and exhibited specimens. The method pursued was to plant quick-growing seeds and plants, such as mustard, cercis, loasa, canariensis, and salvia, in pots; these pots were divided into four groups, one of which was kept entirely in the dark, one was exposed to the influence of the electric light only, one to the influence of daylight only, and one to daylight and electric light in succession. The electric light was applied for eight hours each evening, — from five to eleven, — and the plants were then left in darkness during the remainder of the night. The general result was that the plants kept entirely in the dark soon died; those exposed to the electric light only, or to daylight only, drove about equally; and those exposed to both day and electric light throve far better than either, the specimens of mustard and of carrots exhibited to the society showing this difference in a very remarkable way. Dr. Siemens considers himself as yet only on the threshold of this investigation, but thinks the experiments already made are sufficient to justify the following conclusions:—

(1.) That electric light is efficacious in producing chlorophyll in the leaves of plants, and in promoting growth. (2.) That an electric course of light equal to 1400 candles placed at a distance of two metres from growing plants appeared to be equal in effect to average daylight at this season of the year; but that more economical effects can be obtained by more powerful light centres. (3.) That the carbonic acid and nitrogenous compounds generated in diminutive quantities in the electric arc produce no sensible deleterious effects upon plants enclosed in the same space. (4.) That plants do not appear to require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected during daytime to sunlight and during the night to electric light. (5.) That the radiation of heat from powerful electric arcs can be made available to counteract the effect of night frost, and is likely to promote the setting and ripening of fruit in the open air. (6.) That while under the influence of electric light plants can sustain increased stove heat without collapsing, a circumstance favorable to forcing by electric light. (7.) That the expense of electric horticulture depends mainly upon the cost of mechanical energy, and is very moderate where natural sources of energy, such as waterfalls, can be made available.

In the discussion which followed the reading of the paper it was pointed out that the evidence afforded of the practical identity, as regards vegetation, of solar and electric light, justifies the probability that it would be turned to immediate account by horticulturists, would afford great facilities for the scientific investigation of the influence exerted by light, as compared with other agencies, in promoting the formation of the active principles or most valuable constituents of plants, such as the quinine of the cinchona bark, the gluten of wheat, and so forth. Before concluding his observations, Dr. Siemens placed a pot of budding tulips in the full brightness of an electric lamp in the meeting-room, and in about forty minutes the buds had expanded

[illegible] light, and American invention employing [illegible] fair to witness the jubilee[illegible] candle and all other European contrivances for the shade. It is remarkable that the more successful an electric light is the less public parade it makes; and the Brush lamp has gone into use so quietly that very few even of those in the taste of the matter. About 1,500 of them are now in use. A large number of letters have been received by the writer from cotton-mill and factory owners in this part of the country, in reply to circulars sent out to their experiences with the electric light. From these replies, it does not appear that the electric arc is always a cheaper means of illumination than gas, but sometimes it is remarkably so. The Brush Company's company report that they have never known a case where the electric light was put in that the light, being the first experiment, which ever did that. They never could get light enough in their dingy shops at any reasonable cost, but the volatile light is just the thing for the purpose. They do not know what the light costs them, and do not care. Mr. John Wanamaker has just invested about 13,000 dols. in engines, electric machines, and Brush lamps, and he reports that allowing 5 per cent. interest on the investment, and 5 per cent. for wear and tear, he saves 60 per cent. on his bills for lighting. I have received one statement from a large cotton factory in Rhode Island which has been using the volatile arc light since February, 1876, which is almost incredible. The concern has invested 16,000 dols. in generators and lamps, using 80 lamps in place of about 500 gas-lights. It finds that it now gets a vast increase of light at a cost of only 8,000 dols. a year, whereas it formerly paid out over 28,000 dols. a year for gas. This concern runs all night, and says that the men would not on any account go back to gas-light, because the air of the mill is so much better.—*N. Y. Sunday Times, Chicago Tribune, and Cincinnati Commercial.*

SOME ELECTRICAL MEASUREMENTS OF ONE OF MR. EDISON'S HORSESHOE LAMPS.

BY HENRY MORTON, PH.D., A. M. MAYER, PH.D., AND A. R. THOMAS, AT [illegible]

(Additions and corrections [illegible] 581.)

In reading the above named article in print what we noticed some errors which require correction and some points calling for a more full explanation.

In the second column, ninth line from top, it is said that the loss of weight in one of the electrodes was 1·0021 grammes.

This was, in fact, the amount *gained* by the cathode, the ion of the anode being a little greater. The gain of weight was, of course, what it was intended to take, so that the error was only in the expression, and not in the process or result.

In the next place, in the foot note at the end of the second column, it is simply stated that the average of the maximum and minimum lights in azimuths at right angles and in the plane of the loop was taken as the average luminous power of the lamp. Our reason for this, however, was not mentioned, but was, in fact, that we found by measuring the light at every azimuth varying by ten degrees between 0° and 180°, that this was approximately the true expression for the total amount of light emitted. We are from the article of Profs. Rowland and Barker, in the *American Journal of Science*, that they, assuming certain conditions and discussing the same in a mathematical manner, have reached a different result; but as experiment alone can finally reach to be attained in fact, it is evident that the assumptions on which the mathematical reasoning is based do not include all the conditions present in the experiment.

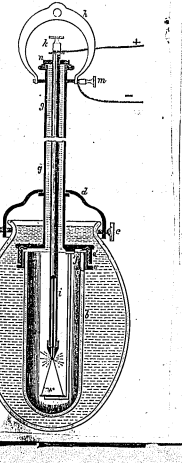
Two other sets of experiments, made since those given in our paper of April 17, in which the candle power of the loop was in its best position, 17·6 and 19·6 candles, corresponding to averages of 11·7 and 12·5 candles respectively, showed a consumption of energy of 0·404 and 0·410 horse power per lamp; or 9·6 and 9·1 lamps per horse power. This would give 213 candles and 220 candles respectively per horse power of electric energy consumed or transformed in the lamp. Those results certainly agree very closely with each other and with our former determinations.

THE BROUGHAM-ANDRE LAMP.

In our account of the exhibition of the André lamp at Stafford House, given in our last issue, we mentioned that the Hon. R. T. D. Brougham had recently made some improvements, which [illegible] fair to make this lamp the best of its kind. The illustration given below will enable our readers to understand the question.

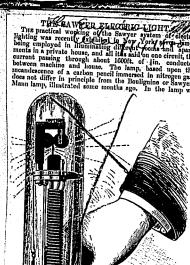
The Lamp Controller.

The lamp is regulated by [illegible] consumed lamps, *F g. 1*, as pointed by insulating material. The interior tube, *i*, contains the carbon rod, 2 mm. in diameter, which falls by its own weight on to the wedge-shaped mass of copper, *n*, connected to the outer tube, *g g*, by the conductor, *f*, the outside cylinder of carbon connected to the negative pole of the battery, the interior to the positive. The cup, *n*, is of vulcanite. A small weight is placed above the carbon rod to assist its descent. The glass globe, *b b*, is furnished at its open end with a brass cylinder, *c*, which is slightly bevelled, while the cup of *h* has a corresponding groove. Between the two is placed an India rubber washer, *f*, so that by screwing up *c* into the cup *e*, the washer is forced into the recess and a good water-tight joint is made. The globe *b b* may be called the lamp globe, to distinguish it from *v a*, which is another glass globe, of any required shape, containing water or some liquid non-absorbent of light rays.



THE SAWYER-STARLING LIGHT.

The practical working of the Sawyer system of electric lighting was recently described in the *Times*, and is now being employed in [illegible] of Messrs. Peek, Frean & Co.'s premises in a private house, and all this within one circuit, the current passing through [illegible] 10001. of lin. conductor between machine and house. The lamp, based upon the incandescence of a carbon pencil traversed in nitrogen gas, does not differ in principle from the Bouliguine or Sawyer-Mann lamp, illustrated some months ago. In the lamp we



now illustrate the glass is 5in. diameter and 10in. high, sealed at bottom by a cement sufficiently fusible to allow for changes by alteration of temperature, and which only softens at 400 deg. The globe is charged by Stillman's method; the cost of charging is considerably less than a cent. The carbon pencil is 7in. in length and about ⅛in. diameter, and is fed up by hand to allow for the slow disintegration that takes place. An automatic regulator is being made; Mr. Sawyer says one pencil will last from ninety days to two years when used but five hours per day. The cost of a pencil is about 1d., and that of replacing and refilling with nitrogen about 10 cents. Our illustration is from the *Scientific American*.

Mr. W. C. Rasmussen [illegible] Edison Lamp.

To the Editor of the Scientific American:—I have read to-day with much interest the results of Messrs. Morton, Mayer, and Thomas's experiments with an Edison electric lamp, published in the *Scientific American* of April 17. The results additional, so far as they relate to the resistance of the loop while giving lights of different intensities and the current required for a light of fifteen candles, are calculable; but those given relative to the cost of one hundred and twenty candles are of no value, because it is (evidently) presumed that the twelve lamps are to be in series in a single circuit, whereas in Mr Edison's proposed system each one of the twelve lamps would be placed in a branch circuit by itself, or, in other words, in multiple arc, and the cost would then be much less than the Stevens Institute experimenters report. The resistance of the armature of Mr. Edison's generator is so small that it may be neglected entirely without seriously affecting the value of the calculations, and the resistance of the leading wires may also be made so small that their neglect will not make any appreciable difference. This being the case, let us see what would be the actual amount of coal required to maintain twelve electric lights in multiple arc, having a total intensity of one hundred and twenty candles.

"Determining upon this conclusion, however, let us determine the electromotive force required to supply a current of 9·905 webers, in a circuit of 76 ohms resistance. Multiplying the current by the resistance gives 9·905 × 76 = 68·78, which would be the required electromotive force in volts. Now, then, place the twelve lamps of 76 ohms resistance each in multiple arc, and their joint resistance will be one-twelfth part of that of a single lamp, or 6·1-3 ohms. As the current generated by the machine is to be divided among twelve branch circuits, so that each circuit will receive a current of 0·905 weber, it is obvious that the total current generated by the machine must be twelve times that required for a single circuit, or 10·860 webers. Multiplying the current by the resistance (as we did for the single lamp) gives 10·860 × 6·1-3 = 68·78, which is the required electromotive force, in volts, and is exactly the same as that required for a single lamp. Hence, even with a Brush or Siemens machine, where forty per cent. of the original energy is lost, the amount of coal required to operate twelve lamps giving an intensity of one hundred and twenty candles is only five twelfths of one pound, instead of five pounds, as calculated by the aforesaid experimenters.

"This shows a pretty large margin below the cost of producing a somewhat less light by coal gas, and in practice the margin would be still greater, for Mr. Edison's generator is said to transform considerably more than sixty per cent. of the original energy into effective current."

The Edison Lamp.—The following results of the experiments made by Professor Henry Morton, [illegible] Mayer and B. T. Thomas on Edison's "eiderdown" lamp are of considerable practical importance:—The resistance of the horse-shoe shaped carbon whilst in its incandescent condition was 79·5 ohms; when cold its resistance was as high as 114 ohms. The current traversing the carbon was 1·079 webers per second, its mechanical value being ·116 horse-power for each lamp. The maximum luminous effect under these conditions was 20·6 standard candles; the mean value being 14·26 candles. Allowing a loss of 40 per cent. in the conversion of mechanical into electrical energy, one horse-power would maintain in action five lamps, each having a mean illuminating power of 14·26 candles, or a total of about 70 candles. These figures alone are sufficient to condemn the Edison lamp; for the worst of regulator lamps would give twenty times the illuminating power (in one form) for an equal expenditure of power; and even the Reguier, or Werdermann lamps, under the most unfavorable conditions, would afford six or eight times as much light as the Edison lamp under the best conditions. The defective result is sufficiently accounted for by the combination of two conditions which are most detrimental from an economical point of view, viz., a comparatively low temperature and large radiating surface.

ELECTRIC LIGHTING.

To the Editor of the Times.

Sir,—To the Editor of the Times.

Sir,—In your article on the Inauguration of the "Jamin Electric Light," in Engineering of June 13th, it is claimed as a feature of the system that the lighting and extinction of any lamp or series of lamps can be effected from a distance without the necessity, "as in the Jablochkoff system," for an attendant to go round from lamp to lamp.

This is clearly to an oversight, as over since the Jablochkoff system was first introduced it has been in use here universally. The fifty lamps on the Embankment and Victoria Bridge are every night lighted and extinguished from the works. The ten lamps at Victoria Station, nearly two miles distant, are also under the same control. In York the 400 lamps which illuminate the Salon, probably the largest illustration of electric lighting, are likewise all controlled from the works.

I am, Sir, your obedient servant,

July 16, 1880. Jules Gaudard,
Managing Director.

The Société Générale d'Electricité,
120, Cannon-street, June 17, 1880.

Galvanic Experiments.—The *Journal of the Chemical Society* says of [illegible] made by M. P. Dreschsel, that the method employed is to [illegible] rapidly reverse the galvanic current from platinum poles through the solution operated upon. By acting in this manner on commercial ammonium carbonate (containing ammonium carbamate) for a period of eight hours, and then evaporating on the water bath, a salt crystallising in fine white needles was obtained. It was found to contain 64·09 per cent. platinum, and is the salt of a platinum base; its composition could not be satisfactorily settled on account of want of material. Concentrated hydrochloric acid gives a bright green, nitric acid a sky blue crystalline precipitate with its solution. About 0·1 grain platinum was dissolved in ten hours by the ammonium carbonate. On working the commutator more slowly, the temperature of the liquid rises, and no precipitate is formed, but by simultaneous cooling a crystalline precipitate occurs, which contains 39·6 per cent. platinum, and is also the salt of a platinum base; this yields an bright green precipitate, but an almost colourless one with hydrochloric acid, consisting of microscopic needles. By operating on a solution of glucose, mixed with sodium phosphate, with very large platinum electrodes, prevented from touching each other by a sheet of filter-paper, the places on the platinum where the paper had rested were found at the end of the experiment to be covered with a brownish translucent substance, easily removable in large plates; this on ignition left a large amount of platinum, but its properties have not as yet been investigated. H. Rolle remarks in a note to the paper that these interesting results have induced him to extend his earlier galvanic experiments, and to study the action of rapid change of poles on a number of salts.

The Electric Light for Steamers.—A very successful application of the electric light has been exemplified in the lighting of the Orient steamship Chimborazo, which left Gravesend on the 25th for Australia. The installation consists of a Gramme machine generating the current by which seven lamps are fed, the machine being 2 nom. horses are worked. Four of these feed the three saloons, and one each the engine-room, forecastle, where the mess of the crew is taken, and chief cabin. The lamps are placed in globes, but a resistance coil and automatic switch renders each independent from its neighbour. Several spare lamps are carried, which can be worked from the same machine. The whole current can also be switched on to a Crompton arc lamp, which can be installed in a special lantern fitted with a reflector. This might be used when in port for the purpose of cargo working. The actual illuminating power of the lamps here is 600 candles, while each of the seven subsidiary lights is about seventy. The whole of the arrangements have been carried out under the superintendence of Mr. Killingworth Hedges, C.E., the incandescent lamps and Gramme machine being supplied by the British Electric Light Company. The extension of the lighting to the other parts of the ship will be completed on her return.

Engineer July 2 1880

ARCHIVE

IMPROVED ELECTRIC LAMP.

The lamp shown in the engraving will be recognized as an Edison lamp, the vacuum globe and the carbon horseshoe being the principal elements. Mr. John H. Guest, a well known electrical inventor of Brooklyn, N. Y., judging from his own experience in fusing platinum with glass in the manufacture of thermostatic fire alarms, concluded that the principal trouble with the Edison lamp would be the entrance of air around the wires passing through the glass of the vacuum globe, devised a simple plan of sealing the joint between the wires and the glass by means of mercury, thus interposing an effectual barrier to the entrance of air at that point.

The invention is so clearly shown in the engraving that scarcely a word of explanation is necessary. In the lamp shown in Fig. 1, the wires that convey the current to the carbon horseshoe are sealed in the ends of curved glass tubes communicating with the globe, and these joints are inclosed in small globes formed on the ends of the glass tubes and filled with mercury.

In this lamp Mr. Guest has made provision partially or wholly preventing the circulation of air, should any remain in the globe after exhaustion with the air pump. The device by which this is accomplished is simply a small globe connected with the lower portion of the lamp globe by a contracted passage, the theory being that the cooler and heavier portion of the air will be drawn into the auxiliary globe by its own gravity.

Fig. 2 shows a lamp in which the tubes that support the wires extend downward into the lamp globe. Those tubes at their junction with the vacuum globe are fused to the platinum conducting wires, and the tubes act simply as lateral supports to the wires inside the globe, allowing the wires to expand freely lengthwise. The tubes are sealed outside the globe in the manner shown in Fig. 1.

Another improvement made by Mr. Guest consists in inclosing the ends of the platinum wire conductors in the ends of the material of the carbon before it is carbonized, the wire being formed into a loop to increase the conducting surface and to insure a good connection with the carbon.

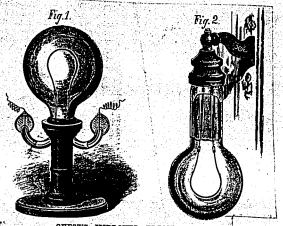


Fig. 1. Fig. 2.

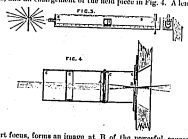
GUEST'S IMPROVED ELECTRIC LAMP.

cannot with propriety be said to be any particular multiple of a green light; nor can one light, which is a mixture of colours, be said with strictness to be a multiple of another, unless the proportions of the colours in the two cases are the same. Captain Abney (*Proceedings of the Royal Society*, March, 1879) has given the results of measurements of the red, blue, and actinic light of electric arcs, in terms of the red, blue, and actinic light of a standard candle. The fact that the electric light is a very different mixture of rays from the light of gas or of a candle, has long been known, but has been ignored in statements intended for practical purposes.

Again, the emission of rays from the heated carbons and arc is by no means the same in all directions. Determinations have been made in Paris of the intensity in different directions, in particular cases. If the measurement is made in a horizontal direction, a very small obliquity in the centre of the positive carbon will throw the light much more on one side than on the other, causing great disturbance in the results obtained.

If the electric light be compared directly with a standard candle, a dark chamber of great length is needed—a convenience not always attainable. In the experiments made at the Smith Institute by Dr. Tyndall and Mr. Douglas, an intermediate standard was employed; the electric light was measured in terms of a large oil lamp, and this latter was frequently compared with a standard candle.

Other engagements have prevented the author *from fairly attacking* these difficulties; but since May, 1879, he has had in occasional use a photometer with which powerful lights can be measured in moderate space. This photometer is shown in Fig. 3, and an enlargement of the field piece in Fig. 4. A lens, A,



of short focus, forms an image at B of the powerful source of light which it is desired to examine. The intensity of the light from this image will be less than that of the actual source by a calculable amount; and when the distance of the lens from the disk is suitable, the reduction is such that the reduced light becomes comparable with a candle or a carcel lamp. Diaphragms, C, are arranged in the cell which contains the lens, to cut off stray light. One of the two is placed at the focus of the lens, and cut off all light entering from a direction other than that of the source; so effectually does it do so, that observations may be made in broad daylight on any source of light, if a dark screen is placed behind it. The long box, DD, Fig. 3, of about 7ft. length, is lined with velvet—the old-fashioned dull velvet—not the new sort with a finish, which reflects a great deal of the light incident at a certain angle. This box serves as a dark chamber, in which the intensity of the image formed by the lens is compared with a standard light, by means of an ordinary Bunsen's photometer, E, sliding on a graduated bar.

Mr. Dallmeyer kindly had the lens made for the author; he can therefore rely upon the accuracy of its curvature and thickness; it is plano-convex, the convex side being towards the source of light. The curvature is exactly 1 in. radius, and the thickness is 0·04 in.; it is made of Chance's hard crown glass, of which the refractive index for the D line in the spectrum is 1·517. The focal length, *f*, is therefore 1·933 inch.

Let *n* denote the distance of the source of light from the curved surface of the lens, and *v* the distance of the image of the source from the posterior focal plane. Neglecting for the moment the loss by reflection at the surface of the glass, the intensity of the source is reduced by the factor $\left(\frac{f}{v}\right)^2$. But $\frac{1}{v} + \frac{1}{n} = \frac{1}{f}$, or $v = \frac{nf}{n-f}$; hence the factor of reduction is $\left(\frac{f}{n-f}\right)^2$. The effect of absorption in so small a thickness of very pure glass may be neglected; but the reflection at the surfaces will cause a loss of 8 per cent., which must be allowed for. This percentage is calculated from Fresnel's formulæ, which are certainly correct for glasses of moderate refrangibility, and for moderate angles of incidence.

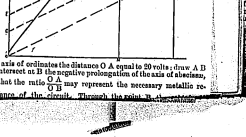
Suppose, for example, it is required to measure a light of 2,000 candles: if it be placed at a distance of 40in., it will be reduced in the ratio 467 to 1, and becomes a convenient and measurable quantity. By transmitting through coloured glasses both the light from an electric lamp and that from the standard, a rough comparison may be made of the red or green in the electric light with the red or green in the standard.

A dispersive photometer, in which a lens is used in a somewhat similar manner, is described in Stevenson's "Lighthouse Illumination;" but in that case the lens is not used in combination with a Bunsen's photometer, nor with any standard light. Messrs. Ayrton and Perry described a dispersive photometer with a concave lens at the meeting of the Physical Society on 12th December, 1879 (*Proc. of the Physical Society*, vol. iii., p. 184). The concave lens possesses, however, no obvious advantage in having a real focus, at which a diaphragm to cut off stray light may be placed.

Efficiency of the Electric Arc.—To define the electrical condition of an electric arc two quantities must be stated—the current passing, and the difference of electric potential at the ends of the two carbons. Instead of either one of these, we may, if we please, state the ratio difference of potential / current

distance of the arc, that is to say, the resistance which would replace the arc without changing the current. But such a use of the term electric resistance is unscientific; for Ohm's law, on which the definition of electric resistance rests, is quite untrue of the electric arc; and, on the other hand, for a given material of the electrodes, a given distance between them, and a given atmospheric pressure, the difference of potential on the two sides of the arc is approximately constant. The product of the difference of potential and the current is, of course, equal to the work developed in the arc; and this, divided by the work expended in driving the machine, may be considered as the efficiency of the whole combination. It is a very easy matter to measure these quantities. The difference of potential on the two sides of the arc may be measured by the method given by the author in his previous paper, by an electrometer, or in other ways. The current may be measured by an Obach's galvanometer, by a suitable electro-dynamometer, or best of all, in the author's opinion, by passing the whole current, or its way to the arc, through a very small known resistance, which may be regarded as a shunt for a galvanometer of very high resistance, or to the circuit of which a very high resistance has been added.

It appears that with the ordinary carbons and at ordinary atmospheric pressure no arc can exist with a less difference of potential than about 20 volts; and that in ordinary work, with an arc about 4 in. long, the difference of potential is from 30 to 50 volts. Assuming the former result, about 29 volts, for the difference of potential, the use of the curve of electromotive forces may be illustrated by determining the lowest speed at which a given machine can run, and yet be capable of producing a short arc. Taking O as the origin of co-ordinates, Fig. 5, set off upon



the axis of ordinates the distance O A equal to 29 volts; draw A B to intersect at B the negative prolongation of the axis of abscissæ, so that the ratio $\frac{O A}{O B}$ may represent the necessary metallic re-

distance of the circuit. Through the point B, the

EDISONIA.

It is an undoubted fact that those connected with Mr. Edison believe in will overcome all difficulties mentioned by critics, and ultimately succeed in producing a cheap and simple electric lamp. In that as it may, the history of the electric light is incomplete without the criticisms that have been urged against his system.

The editors of the *Scientific American* have handed a lamp to Dr. H. Morton, Dr. A. M. Mayer, and B. F. Thurston, M.A., for investigation, with the following result:—The first object, on receiving the lamp, was to determine roughly what amount and character of electric current would be needed to operate it efficiently. With this view a number of cells of a small Grove battery were set up, having each an active zinc surface of twenty square inches, and a platinum surface of eighteen square inches. The lamp being placed in the situation usually occupied by the standard burner in a Bunsen photometer, the battery was, cell by cell, thrown into circuit. When ten cells had been introduced the incandescent wound a dull red, with fifteen cells a bright red, with thirty-four cells the light of one candle was given, with forty cells the light of 45 candles, and with forty-five cells the light of 95 candles, and with *forty-eight* cells 16 candles. Having thus determined what amount of electric current would be required for experiments, arrangements were made to measure accurately the resistance of horseshoe while in actual use and emitting different amounts of light. The resistance of the carbon thread at the ordinary temperature had been already determined as 122 ohms in the usual way, but it was presumed, as had been shown by Matthiessen (*Phil. Mag.*, xvi., 1858, pp. 230, 221), that this resistance would diminish with rise of temperature.

To measure the resistance under these circumstances the apparatus was arranged as follows:—The current from the battery was divided into two branches, which traversed, in opposite directions, the two equal coils of a differential galvanometer. One branch then traversed the lamp, while the other passed through a set of adjustable resistances composed of German silver wires stretched in the free air of the laboratory, to avoid heating. Careful tests of those resistances showed that no sensible heating occurred under these circumstances. Matters being thus arranged, the resistances were adjusted until the galvanometer showed no deflection when the candle power of the lamp was taken especially in the photometer, and the amount of resistance was noted. These measurements were several times repeated, shifting the coils of the galvanometer, and reversing the direction of the current. The results so obtained were as follows:—

Resistances.	Condition of Loop.
121 ohms	Cold.
84 "	Orange light.
80·3 "	$\frac{1}{2}$ candle.
79·6 "	"
75 "	16 "

The photometric measurements was in all these cases taken with the carbon loop at right angles to the axis of the photometer, which was, of course, much in favour of the electric lamp. On turning the lamp round so as to bring the carbon loop with its plane parallel with the axis of the photometer, *i.e.*, the edge of the loop turned toward the photometer disc, the light was greatly diminished, so that it was reduced to almost one-third of what it was with the loop sideways to the photometer disc. Having thus determined the resistance of the lamp when in actual use, it was next desirable to measure the quantity of the current flowing under the same conditions. To do this the current from fifty cells of battery was passed through a tangent galvanometer as a mere check or indicator of variations, and then through a copper voltameter, *i.e.*, a jar containing solution of cupric sulphates with copper electrodes immersed, and then through the lamp placed in the photometer.

Under these conditions it was found that during an hour the light gradually varied from about 16 candles at the beginning to about 14 candles at the end, making an average of about 15 candles, measured with side loop toward disc. The galvanometer during this time only showed a fall of half a degree in the deflection of the needle. Carefully drying and weighing the copper electrodes, it was found that one hall lost 1·0624 grammes. Now, it is well known that a current of one weber takes up 0·00326 gramme of copper per second, which would make 1·1736 grammes in an hour; therefore the current in the present case must have been on the average $\frac{1\cdot0624}{1\cdot1736}$ = 0·905 webers, or a little less than one weber.

Having thus obtained the resistance of the lamp when emitting a light of 15 candles, namely, 75 ohms, and the amount of current passing under the same conditions—namely, 0·905 weber, we have all the experimental data required for the determination of the energy transformed or expended in the lamp expressed in foot-pounds. For this we multiply together the square of the current, the resistance, the constant 0·737305—which expresses the function of a foot-pound involved in a current of one weber traversing a resistance of one ohm for one second—and the number of seconds in a minute. Thus in the present case we have 0·905² = 0·8193, and 0·8193 × 76 × 0·737305 × 60 = 2752·70 foot-pounds. Dividing these foot-pounds per minute by the number of foot-pounds per minute in a horse-power, that is, 33,000, we have 0·08, that is, about eight one-hundredths or one-twelfth of a horse-power as the energy expended in each lamp. It would thus appear that with such lamps as this one horse-power of energy in the current would operate twelve lamps of the same resistance with an average candle power of 16 candles each,* or 192 candles in the aggregate.

Assuming that a Siemens or Brush machine were employed to generate the electric current, such a current would be obtained, as has been shown by numerous experiments, with a loss of about 40 per cent. of the mechanical energy applied to the driving pulley of the machine. To operate these twelve lamps, therefore, we should have to apply more than 1 horse-power to the pulley of the machine, so that when this loss in transformation had been encountered there should be 1 horse-power of electric energy produced. This would call for 13 horse-power applied to the pulley of the dynamo-electric machine by the steam engine. To produce 1 horse-power in a steam engine of the best construction about 2lb. of coal per hour must be burned, and therefore for 13 horse-power 26lb. of coal must be burned. On the other hand, 1lb. of gas coal will produce 5 cubic feet of gas, and will leave besides a large part of its weight in coke, to say nothing of other "residuals," which will represent practically about the difference in value between "steam making" and "gas making coal," so that it will not be unfair to take 5lb. of gas coal as the equivalent of 52lb. of steam coal.

Three 52lb. of gas coal will then yield 260 cubic feet of gas, which, if burned in five gas burners of the best construction, will give from 20 to 22 candles each, or 100 to 110 candles in the aggregate. We have, then, the twelve Edison lamps producing 120 candles and the five gas burners producing 100 to 110 candles, with an equivalent expenditure of fuel.

If such apparatus and system could be worked with equal facility and economy, this world of course show something in favour of the electric light; but when, in fact, everything is this regard is against the electric light, which demands vastly more machinery, and that of a more delicate kind, requires more skilful management, shows more liability to disarrangement and waste, and presents an utter lack of the storage capacity which secures such a vast efficiency, convenience, and economy in gas, then we see that this relatively trifling economy disappears or ceases to have any controlling importance in the practical relations of the subject.

(Additions and corrections to above.)

In reading the above article in print we notice some errors which require correction, and some points calling for a more full explanation. It is said that the law of weight in one of the electrodes was 1·0624 grammes. This was, in fact, the amount gained by the cathode, the loss of the anode being a trifle greater. The gain of weight was, of course, what it was intended to take, so that the error was only in the expression, and not in the process or result. In the next place, in the last note, it is simply stated that the average of the maximum and minimum lights in minutiæ at right angles and in the plane of the loop was taken as the average luminous power of the lamp. Our reason for this, however, was not mentioned, but was, in fact, that we found by measuring the light at every azimuth varying by ten degrees between 0° and 180°, that this was approximately the true expression for the total amount of light emitted. We see from the article of Professors Rowland and Barker, in the *American Journal of Science*, that they, assuming certain conditions and discussing the same in a mathematical manner, have reached a different result; but as experiment shows this result not to be attained in fact, it is evident that the assumptions on which the mathematical reasoning is based do not include all the conditions present in the experiment.

Two other sets of experiments made since those given in our paper of April 17, in which the candle-power of the loop was in its best position, 17·6 and 19·8 candles, corresponding to averages of 11·7 and 13·2 candles respectively, showed a consumption of energy of 0·101 and 0·100 horse-power per lamp, or 9·6 and 9·1 lamps per horse-power. This would give 112 candles and 123 candles respectively per horse-power of electric energy consumed or transformed in the lamp.* These results certainly

* The candle-power being 15 candles in the best position, and 5 candles at right angles to this, the average or general illuminating power of the lamp is 10 candles

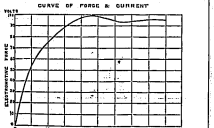
draw a tangent to the curve, touching it at C, and cutting O A in D. Then the speed of the machine, corresponding to the particular curve employed, must be diminished in the ratio $\frac{OD}{OA}$ in order that an exceedingly small arc may be just possible.

The curve may also be employed to put into a somewhat different form the explanation given by Dr. Siemens at the Royal Society, respecting the occasional instability of the electric light as produced by ordinary dynamo-electric machines. The operation of all ordinary regulators is to part the carbons when the current is greater than a certain amount, and to close them when it is less; initially the carbons are in contact. Through the origin O, Fig. 5, draw the straight line O A, inclined at the angle representing the resistances of the circuit other than the arc, and meeting the curve at A. The abscissa of the point A represents the current which will pass if the lamp be prevented from operating. Let O N represent the current to which the lamp is adjusted; then if the abscissa of A be greater than O N, the carbons will part. Through N draw the ordinate B N, meeting the curve in the point B; and parallel to O A draw a tangent E D, touching the curve at D. If the point B is to the right of D, or further from the origin, the arc will persist; but if B is to the left of D, or nearer to the origin, the carbons will go on parting, till the current suddenly fails and the light goes out. If B, although to the right of D, is very near to it, a very small reduction in the speed of the machine will suffice to extinguish the light. Dr. Siemens gives greater stability to the light by exciting the electro-magnets of the machine by a shunt circuit, instead of by the whole current.

The success of burning more than one regulating lamp in series depends on the use in the regulator of an electro-magnet, excited by a high-resistance wire connecting the two adjacent carbons. The force of this magnet will depend upon the difference of potential in the arc, instead of depending, as in the ordinary lamp, upon the current passing. Such a shunt magnet has been employed in a variety of ways. The author has arranged it as an attachment to an ordinary regulator; the shunt magnet actuates a key, which short-circuits the magnet of the lamp when the carbons are too far parted, and so causes them to close.

In conclusion, the author ventures to remind engineers of the following rule for determining the efficiency of any system of electric lighting in which the electric arc is used, the arc being neither exceptionally long nor exceptionally short. Measure the difference of potential of the arc, and also the current passing through it in volts and webers respectively, then the product of these quantities divided by 746 is the horse-power developed in that arc. It is then known that the difference between the horse-power developed in the arc and the horse-power expended to drive the machine must be absolutely wasted, and has been expended in heating either the iron of the machine or the copper conducting wires.

Messrs. Crompton, Preece, and Shoolbred took part in the discussion upon this paper, which, however, unfortunately was commenced at a late hour, when many had left the room. Mr.



Shoolbred exhibited the above diagram, showing the results of experiments at Silvertown, carried out on the A Gramme machine by Mr. K. Gray.

ELECTRIC LIGHTING. 1880

To the Editors of Engineering.

Sir,—The letter of Mr. C. F. Varley, which appeared in your issue of last week, is certainly a curious production. Even your ingenious correspondent, however, has not succeeded in finding any grievance which you are pleased to style a "calumny" against Mr. Varley, but I must still protest against your accusation of "calumny" against Mr. Cornelius Varley's name instead of Mr. C. F. Varley's. You say that Mr. C. F. Varley's letter to the Royal Society in 1867 is conclusive evidence. How can a letter to the Royal Society in 1867 be conclusive evidence as to a patent in 1866? I will now refer solely to the only patent taken out in 1866 for the dynamo-electric machine (No. 3384, dated 27 December 31, 1866) stands in the name of Cornelius and Samuel Alfred Varley. Mr. C. F. Varley's letter to the Royal Society, dated February 28, 1867, merely describes some experiments made on one of Mr. Siemens' dynamo machines. As the date of the latter he states: "In 1860 I established a few machines of two machines I had constructed, and in 1865 or 1866 Dr. Siemens and Mr. Wheatstone exhibited machines for yielding mechanical force from electric electricity without friction. A machine similar in principle to mine, but little different in construction has been exhibited recently under the name of Holtz. One of my machines bears to that machine precisely the same relation that Siemens' and Wheatstone's does to Wilde's."

By no process of reasoning can I see in these lines any claim in the invention of the dynamo machine, or principle on which it is founded; and I am sure Mr. C. F. Varley really claimed such a priority of invention, for in not the

Engineering 4 June

least is he reminded silent at the various discussions on the subject, that have taken place, and in which his brother, S. A. Varley, has continually insisted on his own claim to priority of the invention over Siemens and Wheatstone, on account of the patent standing in his own name and that of Cornelius Varley, and which was alluded to by

Yours obediently,

F. C. Webb.

Engineering 4 June

Progress of Science.

The Brush electric light has been introduced into the South Kensington Museum, in London, and the results are very satisfactory. The experiment has been tried in the hall containing the new fresco by Sir Frederick Leighton, P. R. A. There are eight lamps, three suspended on each side and two in the central line, so that the light is equally diffused. The use of the electric light is spreading. The Victoria docks and Holyhead harbor are to be lighted by electricity. The Royal Navy is adopting Brush's light. Siemens's light has been introduced into the Siam Discovery, Bangkok, as a gift to Jahlechoff's. The arrival of summer has to begin with it a discontinuance of the Siemens light in the reading-room of the British Museum until next autumn. The authorities regard it as a good success.

The Electric Light.—A very successful application of the electric light has been accomplished in the lighting of the Orient steamship Chimborazo, which left Gravesend on the 11th for Australia. The installation consists of a Gramme machine generating the current, by which seven incandescent lamps using Lane carbons are worked. Four of these are fixed in the main saloon, and the remainder in the cabins, the wires being led from the deck to the saloon. The lamps are placed in series, but a resistance coil and automatic switch renders each independent from its neighbour. Several spare lamps are carried which can be worked from the same machine. The whole current can also be switched on to a Crompton arc lamp, which is contained in a special lantern fitted with a reflector. This lamp is intended for the purpose of signalling purposes. The actual illuminating power of the large lamp is 4000 candles, while each of the small incandescent lights is about 75. The whole of the arrangements have been carried out under the superintendence of Mr. Killingworth Hedges, the incandescent lamps and Gramme machine being supplied by the British Electric Light Company. The results of the lighting by the other ports of the ship will be completed on her return.

Engineering July 9 1880

"To resume, my lamp contains several novel points; it lights and relights as often as required; it requires only one circuit for all the neighbouring; it requires automatically those candles candles; it replaces automatically those candles which have burnt out, with entirely new carbons; it does not employ any insulating material of a nature to change the colour of the flames, nor any preliminary preparation of the carbons, this preliminary preparation of the carbons, this preliminary preparation the expense. If we consideredly eliminates the expense. If we consideredly eliminates the source, like all others, variations in the sensing; it does not to a defect in the brilliancy, this will be due, not to a defect in the lamp itself but to a defect in the carbons; these lamp itself but to a defect in the carbons; these variations have disappeared since, thanks to M. Carel, the necessary homogeneity has been given to the carbons. It remains, then, to say how much light can be obtained with a given amount of work, what is the quality of the light and of the heat produced, and to what distance can it be conducted.

"I have employed in these researches a Gramme machine; it was driven by an Otto gas-engine, with which it is possible at any instant to measure the work consumed, which is exactly proportional to the number of explosions; it is sufficient to count them. It is well known that the Gramme machine is composed of two distinct parts; the light machine, is composed of two distinct parts; the light machine, formed by electro-magnets turning rapidly in a ring of iron wound with inducing wires, and an exciter of iron wound with inducing wires, and an exciter with continuous currents, which serves to magnetize the electro-magnets. It only does the preparatory work.

"The current which is produced increases rapidly with the velocity. However small the machine be, the necessary magnetization can always be attained, but one is obliged to expend a considerable amount of power, limited by the heating of the machine. I have succeeded, by theoretical considerations, and have succeeded, by theoretical considerations, and by my latest distribution of the wire, in reducing the heat to a quarter and the expense to a third, producing, at the same time, the same effect.

	First machine.	Improved machine.
Expenditure of horse-power ...	1·394	0·51
Current strength	·78	·76
Velocity	1·447	1·433

"The expenditure of work, reduced to half a horse-power, is insignificant.

"Different types of Gramme machines have been constructed for electric lighting; the large and constructed for electric lighting; the large ones more costly ones will light 24 candles of 1604 mm. size; the smaller ones are capable of working 4 size; the smaller ones are capable of working 4 candles. I have noticed that these last machines are so feeble that they cannot be employed with advantage. When a low velocity is given them, they take little force to drive them; when this speed is increased to 2,500 turns, they absorb about 1/2 horse-power, and, as this work is transformed into heat in the circuits, it is evident that one ought to be able to light a number of lights, and obtain a larger amount of light in proportion, as the velocity is greater.

"However, this is not found to be the case, because the heat developed in the machine is such, that the insulation of its wires becomes destroyed. It was very easy to remedy this defect by diminishing the resistance of the machine and increasing that of the circuit; this has been done with complete success, and allows of 24 lights being obtained with an 8 horse-power engine.

"I will simply give here the results of one of a number of experiments:—

VELOCITY: 1,530.

Number of lamps.	Intensity. Of each lamp.	Total.	Horse-power expended. Total.	Each candle.
1	134	134	2·81	2·81 =
2	113	226	3·60	1·79 =
3	107	321	4·07	1·36 =
4	105	420	4·43	1·11 =
5	95	475	4·70	0·94 =
6	96	576	4·91	0·82 =
7	93	651	5·04	0·72 =
8	92	736	5·11	0·64 =
9	86	774	5·09	0·57 =
10	74	740	5·07	0·51 =
11	70	771	5·04	0·46 =
12	60	720	5·01	0·42 =
13	56	728	4·89	0·37 =
14	50	700	4·60	0·32 =

"It may be remarked that the expenditure of horse-power and amount of light obtained augments up to 9 lamps, after which these two quantities diminish. It is clear that, if we wish to have a greater total amount of light, we must not go beyond this maximum, but if we wish to have a greater number of lights, more feeble, we must exceed it; thus, when we have 14 candles of 0·03 mm. size, a third of a horse-power each only will be required. But it would be better to stop 2 candles of half a horse-power; they are finer and less unsteady, in proportion as the carbons are improved the limit may be overstepped.

"With regard to the light from each lamp, it diminishes with their number; a single lamp with a velocity of 1,500 turns will give a light equal to 134 Carcels, 7 to reduces each to 113, and when the 134 Carcels, 7 to reduces each to 113, and when the number becomes increased to 14, the light from each is diminished to 50; this is the division of a sum total, with a decreasing quotient.

"It may be remarked that this quantity of light is greater than with the ordinary candles; the cause is due to the carbons, which burn with upwards instead of downwards. In one case the light is thrown upwards and is lost; in the other case it is thrown downwards, which is what is required. On the other hand, the flame of the arc, which tends always to rise, leaves the points and does not heat them when they are directed upwards; on the contrary, it envelopes them, and surrounds them with an atmosphere at an enormous temperature when they are turned downwards; this notably increases the amount of light given out. A photometric comparison of two identical candles in the same circuit has shown that the light from the turned down points is five times as great as that obtained with the points turned down. Although their temperature is enormous, the quantity of heat is not great, because the heat focus is small. I have compared in this heat with that of a Carcel, by placing successively this lamp and an electric burner in the same calorimeter. The lights being equal, the combustion of the oil developed 43 times as much heat as did the electric arc.

"It remains for me to speak of the distance to which the light can be conveyed; it is greater in proportion as the velocity of the machine is greater; with 1,500 turns it is possible to introduce in the circuit 1 kilometre of copper wire 002 millimetres in diameter without sensibly diminishing the light; with 2,000 turns 4 kilometres of this wire, or 16 kilometres of wire 001 millimetres in diameter, can be introduced with a similar result. It is thus possible to conceive that a large town can be lighted from a single source.

"The experiments and numerous trials which I have been able to make with the motors and the machines have been a great use upon my resources; I have, therefore, been very fortunate in having been assisted in every way by M. Durrieu, President of the Société du Crédit Industriel et Commercial. I am also equally indebted to the indefatigable exertions of M. Denayrouze, private tutor at the Ecole Polytechnique. I have also to thank MM. Mennesson and Ecouchkoff for having so skilfully assisted me in taking the measurements."

THE JAMIN ELECTRIC LIGHT SYSTEM.

Memoir presented by M. [illegible] to the Academy of Sciences, May 31st, 1880.

[illegible] July 6, 1880.

"I HAD the honour to submit to the Academy, during its meeting of the 17th March, 1879, the principle of a new electric burner. I have since constructed it rests on a slate base which can be fixed in globes quired, and which supports near the base a grooved copper horseshoe, H, H, H, which is bronzed, but, at the same time, sufficiently thick to avoid shadows being cast; at the top of the horseshoe is a hollow soft iron piece, G, whose function is to magnetize and attract a movable armature, E, F. . . . This armature, which is also of soft iron, passes first through a thin copper wire, wound three or four times round in the hollow of the horseshoe piece, H, H; this constitutes the circuit director. It is in the middle of this frame-work that is arranged, as with it that the electric candles, or carbon couples, are placed, between which the arc is formed. There are three of these candles shown, but a greater number can be used if necessary. Each carbon is introduced in a tubular support of copper, so that they are held vertically, being clipped by a spring. The operation of fixing does not present any difficulties. There is no insulating material between the carbons. Those to the right, B, A, ... are fixed and vertical; those to the left a, ... hang freely on joints, b, b', b'', ... the ends of their supports are held by a bar, c, c', which presses them all to one side; the armature, E, F, is connected by a lever, e, b, to this bar, which is pressed to the left by its weight; this causes the carbons to approach and touch against their fixed neighbours. It may be remarked that the contact

LA NOUVELLE BOUGIE ÉLECTRIQUE

DE M. JAMIN

Un appareil, si simple qu'il soit, n'arrive pas toujours immédiatement dans la pratique; nous n'en prendrons pour preuve que le dernier modèle de la bougie Jamin. Nous en parlerons aujourd'hui à nos lecteurs pour compléter l'historique d'un appareil qui, après un an d'études et de perfectionnements, ne répond pas encore, il faut bien l'avouer, aux espérances qu'il avait fait naître. Nul expérimentateur n'était mieux préparé à ces travaux que M. Jamin; par sa haute position scientifique et les travaux qu'il avait pu mener de près, en qualité d'ingénieur-conseil de la Société Alibichoff, le savant académicien possédait à fond cette partie si intéressante de la science électrique.

La première bougie de M. Jamin, présentée à l'Académie des sciences le 28 avril 1870, a été décrite dans le numéro de la *Nature* du 10 mai de la même année. Dans une lettre adressée à notre directeur et publiée dans le numéro du 24 septembre 1870, M. Jamin a décrit un second système, déjà très différent du premier. Enfin, l'appareil présenté à l'Académie le 31 mai 1880 et expérimenté le 5 juin dans le laboratoire de la Compagnie générale d'éclairage électrique, est un troisième modèle de la bougie Jamin, qui, tout en constituant un progrès sensible sur l'appareil primitif, ne répond cependant que très médiocrement aux séduisantes promesses du programme.

Nos lecteurs sont assez familiarisés avec les différents procédés d'éclairage électrique pour comprendre sans figure en quoi consistent les perfectionnements nouveaux de l'appareil.

La nouvelle bougie Jamin se compose d'un cadre directeur formé de quarante spires de fil de cuivre isolé, à l'intérieur duquel sont placées trois bougies de 25 centimètres de longueur environ et devant fournir, par leur allumage successif, un éclairage total de six heures. Ces trois bougies, formées chacune de deux charbons de 4 millimètres de diamètre, sont disposées parallèlement, et la tête en bas, dans le plan du cadre directeur; les charbons du gauche de chaque bougie sont immobiles, les charbons de droite sont fixés sur un support mobile. Au repos, ils sont légèrement inclinés sur les charbons fixes et les touchent par leurs pointes. La partie supérieure du cadre directeur est embrassée par une lame de fer dans rencontrée en U : le passage du courant la transforme en électro-aimant, elle attire une palette qui, par une combinaison de leviers, fait basculer légèrement les trois charbons de droite fixés sur le même support. Le courant traverse le cadre directeur, les bougies fixes, les extrémités en contact, les bougies mobiles, et retourne à la machine ou à la lampe suivante.

Au moment de l'allumage, le courant passe par les trois bougies à la fois, mais il n'y allume qu'une seule, la moins résistante; l'électro-aimant produit l'écartement et maintient les bougies parallèlement. Si le courant cesse de passer, l'électro-aimant devient inerte, lâche son armature; les bougies mobiles s'inclinent, viennent toucher les bougies fixes et l'appareil est prêt pour un nouveau rallumage.

Lorsqu'une des bougies est usée, l'arc voltaïque brûle un petit crochet de laiton qui maintenait en place le charbon mobile : ce charbon, sollicité par un ressort, oscille autour d'un axe horizontal placé à l'extrémité du support; l'éloignement du charbon mobile éteint l'arc, l'électro-aimant devient inerte, les bougies restant en contact, et il se produit l'allumage automatique d'une autre bougie.

Quand toutes les bougies sont brûlées ou qu'il survient un accident à l'une des lampes, un appareil que M. Jamin ne décrit pas, et qu'il nous a été impossible de voir, permet de supprimer la lampe malade ou usée et de la remplacer par une résistance égale. C'est un *parachute ou appareil de sûreté*.

Nous cherchons en vain les nouveautés de cette lampe, sans réserve du cadre directeur, dont nous parlerons tout à l'heure.

MM. Wilde et Ingersoll ont fait, bien avant M. Jamin, une bougie à allumage et rallumage automatique. On trouvera une description complète de la bougie Wilde dans le numéro de la *Nature* du 9 août 1879, et en la comparant, il sera facile de constater l'identité des deux procédés. Nous avons vu fonctionner la bougie Wilde à Londres, un moment même où nous l'avons décrite, tête en bas, comme la bougie Jamin. Le fonctionnement en était aussi bon, mais les charbons s'usaient seulement un peu plus vite que dans la position normale, tête en l'air. A ce moment, sur le fil des comptes rendus, nous avions indiqué l'allumage possible du cadre directeur de la bougie Jamin et de l'allumage automatique de M. Wilde, mais les *expériences* du 5 juin nous ont convaincu de l'inutilité du cadre directeur, qui constitue la seule nouveauté, la seule *personnalité* de la bougie Jamin.

En admettant même que le cadre directeur maintienne l'arc aux pointes au lieu de le laisser se produire entre les pointes mêmes, cet avantage est plus que compensé par l'effet disgracieux qu'il produit et la bande d'ombre qu'il projette tout autour de lui : l'économie de lumière en bas disparaît donc en partie, puisque le point lumineux n'est pas complétement dégagé ; ce cadre directeur introduit aussi dans le circuit une résistance électrique trop importante pour être sans influence sur le rendement.

Le parachute a déjà été réalisé, dès 1878, par M. Rapieff, sous le nom de *safety-apparatus*, par M. Siemens, vers la même époque, et plus récemment par M. Reynier, pour ses lampes à incandescence.

Le système de petit crochet de laiton brûlé par l'arc a déjà été essayé sans succès et ne donnera pas, dans la pratique, les résultats qu'on en attend. En effet, si l'on veut faire avec cet appareil un éclairage des rues, le mécanisme, même très simplifié, serait encore trop compliqué et trop difficile. L'ajustage de ces petits crochets, qui doit se faire *sur place*, en haut d'un candélabre, constitue une difficulté sérieuse; le parallélisme des charbons dépend de cet ajustage, qui doit être assez précis.

Si on veut appliquer l'appareil à l'éclairage domestique, laissons la parole à M. Jamin, qui signalera lui-même, mieux que nous ne saurions le faire, l'inconvénient de son procédé :

« ... C'est ce charbon *désagrégé*, reposant par le cir-

ro de gloriosa.

Correspondencia del Diario de la Marina.

Nueva York, 22 de julio.

EL FERROCARRIL ELÉCTRICO DE EDISON.

Al Director del Diario de la Marina.

Señor Director:

Mi querido amigo el Dr. Manuel Antonio de Carvajal y Costa, de la Habana, me escribe que usted desea que le comunique algunos detalles acerca del ferrocarril eléctrico, que ha sido objeto de mi visita de esta mañana.

Ya sabe usted que soy un entusiasta de este siglo, debido á la fértil inventiva de Thomas Alva Edison, comunmente apellidado "el brujo de Menlo Park."

En cuanto los Sres. D. Leopoldo Carvajal y D. Juan Gualda se enteraron de la practicabilidad del ferrocarril eléctrico, pensaron en darle al pueblo de Marianao de esa adelante, para comodidad de los habitantes que diariamente visitan aquella pintoresca playa. Un tranvía ó ferrocarril de sangre podría tal vez llenar sus objetos pero ni espíritu de empresa de esos caballeros ni patriotico se rebelaba contra la idea de adoptar un sistema ya viejo, cuando el progreso acaba de proclamar la aplicacion de la electricidad como fuerza locomotriz. Quisieron, pues, que Marianao, que está destinada á ser el Newport de la Isla de Cuba, tuviese lo más adelantado y lo más reciente en materia de locomocion, y por poco no hubo de adelantarse al más reciente que el ferrocarril eléctrico sistema de Edison, el cual todavía no ha dado á conocer al público en la última y más prodigiosa de sus invenciones! Se dirá que la aplicacion de la electricidad á la traccion ferrocarrilera es ya un hecho conocido, y que en Berlin en la casa Siemens un ferrocarril elevado cuya fuerza locomotriz es la electricidad; pero esto no destruye el argumento de que Edison ha perfeccionado en su invencion con un sistema más resistente y más adelantado.

Pocos son los que tienen noticia de la nueva invencion de Edison, y menos todavía los que han tenido ocasion de verla funcionar en práctico. Con una actividad que cuadra perfectamente con el apodo de "brujo" que el vulgo le ha dado, Mr. Edison ha construido en sus terrenos de Menlo Park un ferrocarril para el ensayo de su nueva locomotora. El dia que la prensa sobre á los vientos de la publicidad la noticia del suceso prodigio que Mr. Edison tiene en sus terrenos, el villorio ó caserío de Menlo Park volverá á convertirse en otra Meca á donde de toda ca peregrinarán millares de curiosos, creyentes y no creyentes. Hoy por hoy son contadas los que han visto funcionar la nueva locomotora, y entre ellos se cuenta el Sr. D. Leopoldo Carvajal que ha hecho varias visitas al laboratorio de Mr. Edison. De dos de ellas tuvo el honor de acompañarle el corresponsal del DIARIO, deseoso de recoger y comunicar á sus lectores algunos datos referentes á una invencion tan importante, y el resultado de esa visita ahora hoy de tema principal á esta carta.

Encontramos á Mr. Edison en el taller de maquinaria dirigiendo el trazado de unos planos, y mas tarde con esa afabilidad nunca fatiga, que constituye uno de los rasgos principales de su carácter.

El Sr. Carvajal, le comunicó nuestro deseo de conocer los pasos que en el ramo de locomotoras y que la pone en comunicacion con los dos fabricantes de talento y de vivir de la Habana

trasitos habrán y otro espíritu emprende-
dor construirá allí algunos lindos cottages
chalets con sus jardincillos, folletos anun-
ciando á las familias que los alquilan para toda la temporada. ¿Porqué no ha de tutar la isla de Cuba en Newport, como los Estados Unidos, en Brighton, como Inglaterra, en Biarritz, como Francia y en San Sebastian, como España?

Al espíritu de empresa toca contestar á estas preguntas. Todo podrá ser si los señores D. Leopoldo Carvajal y D. Juan Conill encuentran émulos é imitadores. A dichos señores faltaría por las proyectadas mejoras que piensan introducir en Marianao, y deseo que el ferrocarril eléctrico que allí construyan obtenga el buen resultado que marcho.

Si el espíritu de empresa ha sido la varita mágica que en pocos años ha trasformado el arenal de Coney Island en un palacio de hoteles-palacios que atrae gente de todas partes de los Estados Unidos, porqué no ha de poder el mismo talismán cambiar la faz de la playa de Marianao, trasformarlo allí atractivos veraniegos que llamen á los viajeros de la isla de Cuba que van á embarcarse en la Habana para dirigirse á puntos balnearios del extranjero? ¿Es acaso imposible que donde se proyecta introducir la luz eléctrica y el ferrocarril eléctrico y se intenta hacer una ensenadada para impedir que los tiburones se acerquen á la orilla, se construya también un cómodo y espacioso hotel á estilo americano, con un parque donde haya ruleta, todas las noches? Y si ahí no se

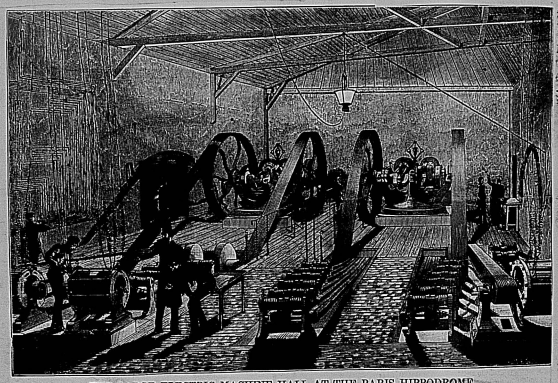
THE LARGE ELECTRIC WORKS OF PARIS.

THE STORES OF THE LOUVRE—THE HIPPODROME.

If we desire to obtain some idea of the progress made by the electric light during the last few years, we shall have to go down into the sub-culture under the stores of the Louvre, and also pay a visit to the magnificent electrical works of the Hippodrome. These two great establishments have adopted systems of electrical lighting under special and very different conditions; and, in describing them, we shall show within what limits the electric light, when properly applied and managed, may prove serviceable; and we shall see, too, whether or not it is capable of advantageously replacing the other methods of artificial lighting that are now in use.

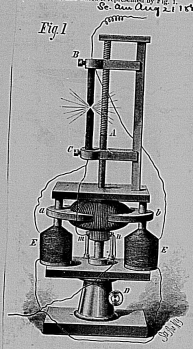
LIGHTING OF THE STORES OF THE LOUVRE.

It is to the stores of the Louvre that belong the honor of the first experiments made with the Jablochkoff candle. This curious, which was modestly began itself candle. This curious, which was modestly began with a few candles and one Alliance machine, now embraces within a few candles and one Alliance machine, now embraces within a few candles and one Alliance machine, now embraces within



THE LARGE ELECTRIC MACHINE HALL AT THE PARIS HIPPODROME

W. Tchikoleff, the head of the electric lighting department of the Russian artillery, has described, in *La Lumière Electrique*, a new lamp, the design of which was lately brought before the physical section of the Moscow Society of Naturalists, and which is represented by Fig. 1.



TCHIKOLEFF'S ELECTRIC LAMP.

E E' are electro-magnets disposed like those on the other systems, and having poles, a b, spread out in circular form as in the Gramme machine. K is a Gramme or Siemens ring, the rotary motion of which causes the carbons to move through the intermediary of a double thread screw, A, and two nuts, B C, which carry the carbons. Lastly, D is a regulating screw, for the purpose of raising or lowering the luminous focus.

The current passes from the positive pole of the generator to the negative pole by three derivations, one of which includes the arc and traverses the ring by means of the contact pieces, m n, while a second, also including the arc, excites the electro-magnet, E (or both electro-magnets in a given direction); and a third which, without passing by the arc, influences the high resistance magnet, F (or both magnets in contrary directions), so that the action of this magnet upon the ring shall be in a reverse direction to that of E.

In consequence of this arrangement the action of the electro-magnets upon the ring, K, is, among all, when the arc possesses its normal resistance; but when the resistance of the arc augments, the action of the electro-magnet, E, becomes weakened, allowing F, to preponderate, and the ring, K, will rotate so as to bring the carbons into closer proximity. The contrary effect, will, of course, be produced if the resistance of the arc should diminish.

Experience has shown that with such a lamp it is possible to obtain, with regularity and safety, a good electric light with twenty-four Bunsen cells, and at first with even twenty cells. Some of these lamps have been in use in the Russian artillery since 1877. This lamp may also be constructed on the principle of the Wheatstone balance.

The form of this lamp intended for public lighting is represented by Fig. 2. The rod, A, with the upper carbon holder, works by the effect of its own weight. When the current traverses the lamp the distance between the two carbons is maintained by the aid of helical coils, but these coils and the toothed wheel which controls the movements are worked, as in the former case, on the principle of derivation. When the current is interrupted, the carbons come into contact by the effect of the weight of the rod, A.

Certain details of construction have been omitted in this description, but enough has been given to make the principle clear.

To sum up, the advantages of this lamp may be enumerated as follows:

1. Its construction is extremely simple; it is free from clockwork mechanism, springs, and electrical contacts.

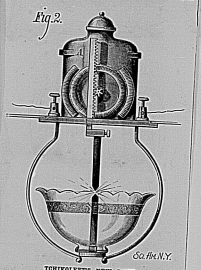
2. It does not require preliminary regulation nor any manipulation before or during its working.

3. Several of these lamps may be arranged in series in a circuit, and they are always in due relation with the intensity and the tension of the current which is to act upon them.

4. The lamp can work with comparatively weak currents, and also produce a very powerful light when the power of the current is augmented.

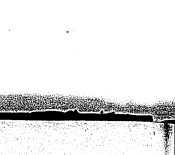
The inventor is convinced that the problem of the divisibility of the electric light by means of lamps having a voltaic arc can be solved only with the lamps based on the principle of the derivation of the current, which he discovered prior to Messrs. Lontin and Siemens.

Lamps with movable cartons, offering a certain resistance between their polar extremities, are, moreover, far preferable, from the point of view of divisibility, to lamps with fixed carbons, which may offer great variations in the resistance of the arc, in consequence of impurities, the action of the wind, etc. These variations may, in fact, be greatly reduced in the former description of lamp, and it is not necessary with them to employ currents of such high tension, or, if such currents be employed, additional lamps may be inserted in the circuit.



TCHIKOLEFF'S NEW LAMP.

THE ELECTRIC LIGHT IN PARIS FOR THE 24TH OF JUNE.—On this occasion nearly all the inventors of apparatus and the companies for electric lighting were represented. About forty Jablochkoff candles were arranged in groups at the Bois de Boulogne; the great lamps of M. Lontin were placed on the July column at the Place de la Bastille, and six more on the boulevard Montparnasse; the Serrin lamp was conspicuous on the Place de la République, and at the *Mairie du Temple*, whilst the modification of this lamp by M. Suisse was to be seen burning in the open air at the rue Saint-Sébastien. M. Jamin lamps figured at the *Magazins réunis*, and others were observed in Belleville; Messrs. Siemens Brothers had fourteen of their differential lamps at the *Palais Royal*, and four on the *place de la Bourse*; the *loggia* of the Opera was illuminated by six Dubosco regulators; the Compagnie Meritens and the



The Jamin Electric Light.
Lately one of the electric light companies of Paris made recent trials of the electric light, and the Jamin lamp was used. Singular, however, to say, the inventor of the lamp, one of the French delegates at the celebrated Electrical Congress at Paris, the object being to test the efficiency of the various electric lamps, and the distinguished gathering of ministers and notabilities connected with science, industry and public works were present on the occasion. At 10 o'clock a method of working, the number of lights to be used, by various experiments, the trial proceeded to the use of the Jamin lamp. The result was the following results could be obtained: The whole of the lamps placed on the same circuit could be lighted and extinguished at once, each formed by two rods of carbon 12-100 in. thick, one of which, were to be pressed back by a brass clip, would the electric current which forms the arc. When the candle has burnt to the end, the current consumes the brass clip, the carbon rods are separated by the spring, and the arc is transmitted to the adjoining candles. By this method the light can be kept up for an almost unlimited time. The lighting or re-lighting of the lamps is effected instantaneously by means of automatic mechanism, and if one of these should by any accident become extinguished, the others are not in any way affected thereby, but continue to burn with undiminished brilliancy. The light, which is well divided, is capable of being regulated at will from the soft light of a number lamps, to that of the full power of 300 lamps. The electric current is conducted to a distance of 24 miles from the electric source by means of a copper wire, differing in thickness according to circumstances, by a wire double that thickness. The experiments made at the last trial served to satisfactorily prove the steadiness of the light obtainable with the Jamin lamp. With respect to the cost of working, it was stated by the inventor that each lamp, which is equal to only one-half the power of a Jablochkoff candle, consumes, the electric candles are used, as at the Place de l'Opera in the Place du Theater Français, in Paris, and careful experiments have demonstrated that the system is capable of effecting a saving of one-third, or at least a quarter, as compared with coal gas, or at least a fifth of gas. The results of the illumination by means of electricity, as exhibited at the trial, were declared to be satisfactory, and it was proposed to promote at once the important position of forming a vast cheap and manageable method of illuminating suitable for factories and other large establishments and towns.

IMPROVEMENT IN THE EDISON LAMP.—A Mr. J. H. Guest, of Brooklyn, has been highly successful in making the "Edison lamp" perfect. He thought the principal trouble would be the entrance of air around the wires at the point of fusion in the glass, and to remedy this encloses the joints in small globes formed on the ends of the glass where the wires pass through into the vacuum globe. These globes are partially filled with mercury in order to ensure an air-tight joint. We see no reason why the cheaper material, water, should not be used instead of mercury, but we may also point out that this does not prevent the disintegration of the carbon, which is *the* weak point in the lamp.

THE ELECTRIC LIGHT IN BOMBAY.—The *Bombay Gazette*, one contemporary, the *Bombay Gazette*, is now constantly lighted by electricity. When the preliminary trial was made, says the *Gazette*, the result was found to be so satisfactory that we determined to use this beautiful light in the composing and machine rooms, and steps were taken to procure the additional motive power necessary. To drive the printing machines of the office an ordinary three or four horse-power engine was sufficient, and no engine of the same capacity would have been sufficient to drive the Gramme magneto-electric machine. It was deemed better to get an engine able to drive both at once, and with plenty of power to spare, so as to allow of future developments. One of Robey's semi-portable engines of eight horse-power was selected. The engine up, M. Verne, the chief engineer of the Indian Electric Light Company (*Limited*), a branch of the Société Generale d'Electricité of Paris, put up one of Gramme's eight-light magneto-electric machines, and made the connections with two lights in the composing room, one in the machine room, and one at the entrance. This leaves a reserve of four lights, which may be used hereafter if required. The connections made and steam up, the turning of a handle flooded the composing room, the machine room, and the entrance in the brightest and purest light, each lamp having the photometric value of fifty ordinary gas-jets. Every evening since the light was first used it has been turned on and used in the same way without trouble. There is abundance and superabundance of light, and the heat and vitiation of the atmosphere inseparable from the use of all other systems of illumination are entirely done away with. The Jablochkoff candles are used for the conversion of the electricity into light. The Société Generale is at present making arrangements with the Maharajah of Cashmere to light Jummoo with electricity. As a preliminary, His Highness's palace will be lighted up, and if all goes well the city, or at least its principal quarters, will be lighted. The light is in use at Rangoon in several rice mills, and in the private house of one gentleman. The company was employed by Sir Richard Temple to light the bridge-makers at Jhelum and elsewhere at night on the Candahar line.

DISTRIBUTING CURRENTS FOR ELECTRIC LIGHTS.—Among the many recently-introduced improvements calculated to make electric illumination permanently practicable, says the *Mining Journal*, is one by the Société Générale d'Electricité, of Paris, which is specially worthy of attention; it is a disconnecting and commutating apparatus for distributing currents to the lamps, and is so arranged that if one of a number of lamps or groups of lamps should by accident become extinguished, or should its carbons break or be consumed, this lamp is automatically thrown out of circuit, and the next in order is brought into circuit. When the lamp is of the Jablochkoff kind there is attached to the clamp that holds the candle a strip made of two metals having unequal degrees of expansion. The strip is bent in U form inverted, and is attached by one of its limbs, presenting its bend near the lower end of candle. When the candle is burnt down to this point, the heat of the voltaic arc acting on the bent strip causes it to partially unbend, so that its free limb comes against a contact screw, and thus establishes a circuit of less resistance by which the electricity passes, without continuing to pass through the residuary carbons of the candle. The free end of the bent strip may have attached to it a spring, which is usually held in a bent position by butting against a stop, until by the change of shape of the strip it is released from the stop, whereupon it springs against the contact screw and short circuits the current. The commutator whereby the candles are brought successively into circuit consists of a vessel of ebonite or other non-conducting material, divided into a number of parallel compartments, each containing mercury, connected by wire with one of the lamps or candles. Above this vessel is mounted a shaft which extends over all the compartments; it has on it a metallic disc which dips into the mercury of the first compartment, and at intervals along it, corresponding to the distance of each compartment from the next, it has a number of metallic pins projecting from it, these pins being arranged helically on the shaft, so that when the shaft is turned round, as one pin is leaving the mercury in one of the compartments the next pin in order is entering the mercury in the next compartment. On the shaft is an escapement which, worked by an anchor on the armature of an electro-magnet. The armature of a second electro-magnet is attached to a lever, which carries at its end two metal pins immediately over two cups containing mercury. Usually while one lamp of a series is in action the electric current for the lamp passes through the coil of this second electro-magnet, which by attracting its armature, keeps the metal pins out of the mercury. When, however, from any cause the lamp becomes extinguished, the second electro-magnet, no longer excited by an electric current passing through its coil, ceases to attract its armature; the armature lever thereupon moves so that its pins dip into the mercury cups, giving passage for the electric current to the first electro-magnet, the armature of which, moving the anchor, turns the escapement wheel and its shaft partly round. By this movement of the shaft the one of its pins which was in the mercury of one compartment, closing the circuit of the lamp that was in action, is withdrawn from the mercury, so that this lamp becomes excluded from the circuit, and the next pin on the shaft being now immersed in the mercury of the next compartment, closes the circuit for the next lamp in order. Immediately on that lamp coming into action the electric current again passes through the coil of the second electro-magnet, which, attracting its armature, withdraws the pins thereof from the mercury cups in which they were immersed, and so causes the first electro-magnet to be excluded from the circuit until it is again brought into circuit by the extinction of the active lamp or candle. Thus, as lamp after lamp comes to act the lamps are brought successively into circuit. It is convenient to number these lamps consecutively, and to fix on the shaft an index which, as it is moved by the shaft over a dial marked with numbers corresponding to those of the lamps, indicates at any time which of the lamps is in action.

THE ELECTRIC LIGHT AT ST. ENOCH STATION.

To the Editor of Engineering.

Sir,—With reference to your article on the Electric Light at St. Enoch Station, Glasgow, I should like to remark that the length of lantern is necessarily determined by the length of what they are constructed to enclose; length in this case is of little importance in the lantern itself, whilst it does not influence the illuminating effect at all.

Kindly allow me to remark that the British Electric Light Company, Ltd., as your article might lead one to suppose, have up to the present used a lamp exclusively; the company are not specially interested in any one lamp, which is a guarantee that the method best adapted to any particular work will in each case be used by them. The fact, however, that I selected Mr. Crompton's lamp for work as important as the illumination of St. Enoch Station speaks more for the lamp than if the company were specially interested in it.

Your obedient servant,

H. Hedgeffe Wade,

Engineer to the British Electric Co., Ld.

41, Parliament-street, Westminster, July 28, 1880.

Notes.

ELECTRICITY ON BOARD SHIP.—A steamer named the *Columbia*, which has just been completed at Chester, Pennsylvania, for the Oregon Railway and Navigation Company, has several novel and interesting applications. Thus, the Edison electric light is adopted throughout the ship. We learn from the *Scientific American* that the lamps are 120 in number. The lights of the state-rooms are under control of the steward on the out-side. The state-rooms on the upper and lower decks are on separate circuits, and so are the saloons. The lamp-fixtures are of the same form as those used for oil lamps, and by an ingenious contrivance they are adapted to either the electric or oil light, so that should the former fail in any way, the latter may be at once substituted. The electric lamp globes are frosted lightly by dipping in hydrofluoric acid. The desirability of electric lighting on shipboard, where fire risk elements are necessarily small, is obvious. The *Columbia* has further an electric hand light, consisting of a Maxim electric light. All the rooms are fitted up with electric calls, and the officers, smoking-room, &c., are provided with telephones, the smoking-room being in connection with the steward's room, and the captain's with the chief engineer's, purser's, and steward. An electric call-bell on the bridge enables the captain to tell, by simply ringing a button, whether the engine is going ahead or astern, and at what speed. The steering gear has connection with the foreign hoister, but with self-acting steadiness. The elevator for discharging cargo are new in design, and the running engines at the posts are arranged so that a loaded truck runs from the lower hold into the deck entirely by steam. The arrangement of berths is similar to that in a Pullman palace car, and when the berths are not in use they are folded out of the way. The system of water-supply for fire, &c., is very complete; and a new kind of still is used which is capable of supplying 1,000 gallons of pure fresh water daily. The *Columbia* is 324ft. length, 38ft. beam, 23ft. depth of hold, and 3,200 tons measurement.

THE printing offices of the *Neue Freie Presse* at Vienna are now lighted with Siemens' divided electric lamps.

CURIOUS MAGNETIC EXPERIMENT IN MAGNETISM.—M. Ohaikal has described a curious magnetic experiment to the French Academy. Two magnetic needles are suspended over water in a vessel by fine threads attached to needles poles. Their poles are opposite, and are distant from each other by an amount a little greater than the sum of their radii of mutual attraction. The water is gradually brought up over them by means of the tube of caoutchouc connected with the vessel and wound on a drum. When immersion commences, the needles approach each other by their immersed parts, and when the immersion has reached the third or fourth of the needles' length, they touch together. The explanation seems to be, that when hindered the orientation of the needles was their own weight; and the forces of gravity being weakened by the immersion, the magnetic forces become manifest. If the needles are suspended by their poles of the same name, a corresponding though opposite phenomena is ob-

THE JAMIN ELECTRIC LIGHT.

June 15/1880

On Friday, June 4th, some trials of the Jamin Electric Light were made in the laboratory of the Compagnie Générale d'Eclairage Electrique, 27, Avenue de Moine. A large concourse of scientific notabilities was present, including M. Gambetta, M. Durrieu, the Minister of Public Instruction, Members of the Institute, Perpetual Secretary of the Academy of Sciences; Vaucorbeil, Bergnet, Renier, Hervé-Mangon, Director of the Conservatoire des Arts et Métiers; Antonin Proust; Admiral Mouchez, Director of the Observatory; Desain, Professor of Physic at the Sorbonne; Freisy, Director of the Museum; Daubrée, Director of the School of Mines; Hébrard, senator, Director of the *Temps*; Gailly, senator; Debesh, Martial

MACHINES DYNAMO-ÉLECTRIQUES

Et régulateur à courants continus Jules Richard

DE MM. SIEMENS ET HEFNER-ALTENECK

La machine et le régulateur que nous allons décrire aujourd'hui s'emploient en Angleterre et en Allemagne comme on emploie en France la machine Gramme et le régulateur Serrin. Nous devions donc signaler ces deux appareils aux lecteurs de *la Nature* pour compléter ce que nous avons déjà dit à diverses reprises sur l'éclairage électrique, et les tenir au courant de l'état actuel de la question.

La machine de M. Hefner-Alteneck, construite par M. Siemens, est une machine dynamo-électrique à courant continu analogue, quant au principe du fonctionnement, à la machine de M. Gramme. Elle en diffère par la forme des inducteurs et surtout par la manière dont le fil est enroulé sur l'anneau mobile.

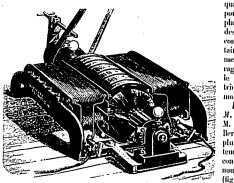

Fig. 1. Machine dynamo-électrique de M. Siemens (moyen modèle).

Les inducteurs sont formés de deux électro-aimants à pôles consécutifs composés de barres de fer doux réunies au bâtis de fonte de l'appareil, qui forme enfin la culasse extérieure.

La forme aryuée des pôles répartit mieux le champ magnétique, le rapproche des bobines, ce qui est une condition favorable à la production de courants puissants. Les inducteurs, dans les machines de grande et de moyenne puissance, sont disposés *horizontalement*, ce qui donne de la stabilité à l'appareil. Dans les machines du plus petit modèle, employées plus spécialement pour exciter les inducteurs des machines à courants alternatifs, et représentées précédemment dans *la Nature*, les inducteurs sont verticaux, pour ne pas trop rapprocher la bobine du sol.

La bobine induite présente une assez grande longueur et se compose d'une série de bobines partielles reliées à un collecteur Gramme. Le fil induit ne recouvre que la partie extérieure de la carcasse en fer sur laquelle les bobines sont enfilées. On utilise ainsi beaucoup mieux l'inducteur, l'enroulement des bobines est très simplifié et les difficultés que présente le rentrage de l'anneau Gramme disparaissent complétement.

Dans les premières machines construites en 1875, l'anneau en fer était fixé dans l'espace et placé à l'intérieur de la bobine tournante, mais dans les modèles plus récents de 1875 et de 1876, on a remarqué à cette disposition compliquée pour recevoir à un anneau tournant avec la bobine, ce qui fait remonter la machine Siemens dans le système Gramme, à laquelle elle a emprunté d'ailleurs les collecteurs et les balais.

Suivant les dimensions de la machine, on peut alimenter des lampes donnant de 200 à 800 becs Carcel en un seul foyer, dépensant de 2 à 5 chevaux de force motrice.

En changeant la nature du fil des inducteurs et des induits, on peut, pour une machine donnée, augmenter la quantité et diminuer la tension, ou inversement, suivant que le courant doit avoir de la quantité, comme pour la galvanoplastie et l'incandescence, ou, au contraire, une certaine tension, comme pour l'éclairage électrique et le transport électrique de la force motrice à distance.

Régulateur de M. Siemens. — M. Siemens, de Berlin, a construit plusieurs régulateurs à courant continu. Celui que nous reproduisons (fig. 2), imaginé par M. Hefner von Alteneck, ingénieur de la maison Siemens, est le dernier modèle adopté par les constructeurs en 1876.

La lampe que nous avons décrite dans *la Nature* est destinée plus spécialement aux courants *alternatifs* et à la division de la lumière; celle-ci est *monophote*, c'est-à-dire qu'elle ne permet de disposer qu'*une seule lampe* sur le circuit des machines qui l'alimentent. Le mécanisme reste le même pour les trois types de machines employées; les dimensions seules varient, suivant que l'appareil est appliqué aux phares, à la guerre, à la marine, à l'industrie, etc., et que l'on a besoin de foyers plus ou moins puissants.

Dans ce régulateur à courant continu, le mouvement d'approche des charbons est produit par le poids du porte-charbon positif, qui sert de moteur. Le mouvement d'écartement, au contraire, se produit par un appareil qui n'est autre chose qu'un petit moteur électrique, et dont nous allons examiner maintenant le fonctionnement.

Les organes principaux du régulateur Siemens sont : les deux porte-charbons A et B, un mouvement d'horlogerie animant par le poids du porte-charbon A et dont le dernier mobile est une roue à rochet dont la vitesse de rotation est modérée par une roue à ailettes I.

Le courant de la machine arrive par la borne G, traverse un électro-aimant E, dont on n'a représenté qu'un des noyaux, arrive par le rhéostat R à la lampe au porte-charbon positif A, traverse l'arc et revient à la machine par le porte-charbon B, en garniture isolée, et la borne Z, reliée au pôle négatif.

Au moment où l'on envoie le courant dans la lampe, les charbons sont en contact; le courant est très intense; il attire son armature cylindrique, fixée à un grand levier vertical pivotant autour de Y. Ce levier bascule de droite à gauche autour de Y, et un cliquet Q, fixé à son extrémité, fait tourner la roue I d'une dent en sens inverse du mouvement du charbon, mais à ce moment il se produit un contact en X; le courant traverse alors directement la dérivation de faible résistance produite par ce contact, et l'électro-aimant devient inerte. Sous l'action du ressort P, réglé par la vis B, le levier reprend sa position première; mais alors le contact en X est rompu, l'aimant est actionné de nouveau ; il attire son armature, et le tout se donne de nouveau d'une dent dans le sens favorable à l'écartement des charbons. Il se produit donc ainsi une succession rapide de mouvements, comme dans le tremblement des sonneries électriques, qui ont pour effet d'écarter les charbons très rapidement jusqu'à une distance normale, pour laquelle l'appareil est réglé. Lorsque cette distance est atteinte, le cliquet Q produit l'embrayage et maintient, le cliquet Q produit l'embrayage et maintient le levier en cet état. Alors très près du tient l'écartement. Le levier est alors très près du contact X, et si l'appareil est bien réglé, on sent, en mettant le doigt en N, une sorte de *frémissement* dû à la rupture et au rétablissement du courant, qui est l'indice le plus certain de ce bon réglage. Si l'arc s'allonge, l'armature tend à s'écarter de E et produit le déclenchement de la roue I, ce qui permet le rapprochement des charbons.

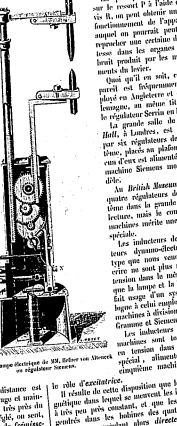

Fig. 2. Lampe électrique de MM. Hefner von Alteneck et régulateur Siemens.

On dispose dans cet appareil de trois moyens de réglage :

1° La tension du ressort P ;

2° La distance de l'armature à l'électro-aimant E, distance que l'on règle à l'aide d'une vis K ;

3° Le contact X, réglé une fois pour toutes par le constructeur d'après la course du levier et la longueur des dents du rochet.

En pratique, en agissant sur le ressort P à l'aide de la vis B, on peut obtenir un bon fonctionnement de l'appareil, auquel on pourrait peut-être reprocher une certaine délicatesse dans les organes et le bruit produit par les mouvements du levier.

Quoi qu'il en soit, cet appareil est fréquemment employé en Angleterre et en Allemagne, au même titre que le régulateur Serrin en France.

La grande salle du *Albert Hall*, à Londres, est éclairée par six régulateurs de ce système, placés au plafond; chacun d'eux est alimenté par une machine Siemens moyen modèle.

Au *British Museum*, il y a quatre régulateurs de ce système dans la grande salle de lecture, mais le couplage des machines mérite une mention spéciale.

Les inducteurs des générateurs dynamo-électriques de type que nous venons de décrire ne sont plus montés en série dans la même circuit tension dans la même circuit que la lampe et le balast, ou bien suivant le système adopté à celui employé dans les machines à division de Lontin, Gramme et Siemens.

Les inducteurs des quatre machines sont donc disposés en tension dans un circuit spécial, alimenté par une cinquième machine qui joue le rôle d'*excitatrice*.

Il résulte de cette disposition que le champ magnétique dans lequel se meuvent les inducteurs est à très peu près constant, et que les courants ne sont pas influencés dans les bobines des quatre autres machines, correspondant alors aux inducteurs, sont entièrement indépendants les uns des autres, sont même beaucoup plus constants que si chaque machine avait son inducteur dans son circuit propre. Les machines fonctionnent alors comme de véritables

LANTERNE DE DIFFUSION

POUR LA LUMIÈRE ÉLECTRIQUE

Nous avons assisté récemment à de très intéressantes expériences d'éclairage électrique, et nous avons remarqué les excellents effets produits par la lanterne de *diffusion* représentée ci-dessous ; M. l'ingénieur Clémandot, qui l'a inventée, a bien voulu nous écrire sur notre demande la lettre suivante, que nous sommes heureux de publier.

G. T.

Paris, le 9 juillet 1880.

Monsieur,

Je me préoccupe depuis longtemps déjà des moyens à employer pour obtenir une bonne diffusion de la lumière électrique, c'est-à-dire d'utiliser cette lumière qui est tellement intense, si elle n'est pas répartie uniformément, tamisée, *diffusée*, c'est le mot, qu'elle ne donne que des résultats très imparfaits et hors de proportion avec les dépenses faites pour la produire, comme avec son intensité toute particulière.

Les globes opaques employés ont rendu à n'en pas douter de grands services, mais ce n'est pas, on peut dire, par diffusion qu'ils opèrent ; ils deviennent *lumineux eux-mêmes*, et comme ils sont employés sous un gros volume, ils deviennent nécessairement éclairants. Il y a bien, dans ce cas, une certaine quantité de lumière tamisée, mais eu égard à la lumière produite, il n'y en a pour ainsi dire que la moitié d'utilisée, et les expériences photométriques ont prouvé qu'il y avait environ 45 pour 100 de la lumière produite absorbée. La lumière électrique, si coûteuse à produire, est donc à moitié détruite par un accessoire indépendant de la lumière elle-même.

Le principe qui a servi de base à mes recherches, est celui qui préside à la répartition, à la diffusion de la lumière solaire. En examinant cette question, n'avez-vous pas à remarquer que ce sont les nuages placés entre nous et le soleil qui se chargent le mieux de nous répartir sa lumière, de ménager nos yeux, en peut dire, et cela est si vrai, que quand il s'agit de photographie, par exemple, c'est par un temps relativement couvert, c'est-à-dire par la lumière blanche, la lumière diffusée, que cette opération, dans laquelle le soleil se charge d'être notre dessinateur, réussit le mieux.

Le problème à résoudre était donc celui-ci : envelopper la lumière électrique d'une vapeur remplissant le rôle de nuages, c'est-à-dire nous tamisant, nous diffusant cette lumière. J'ai donc enveloppé la lumière, l'arc voltaïque, d'une double enveloppe, dans laquelle j'ai introduit une matière solide, il est vrai, mais tellement fine, tellement ténue, que c'est une substance solide pour ainsi dire vaporeuse. C'est du verre filé par des procédés particuliers qui donnent pour résultats des fils d'une finesse telle que chacun d'eux mesure 6 à 8 millièmes de millimètre, fils qui sont 175 fois plus fins qu'un cheveu et 45 fois plus fins que le plus ténu fil de soie.

Lanterne de M. Clémandot pour l'éclairage électrique.

Les premiers essais de mes procédés de diffusion ont été faits dans les grands magasins du Louvre, grâce à l'obligeance et à la libéralité de leurs propriétaires. J'avais imité un nuage, pour ne pas sortir des habitudes ordinaires, dans des globes en verre de 40 centimètres de diamètre ; mais la pratique de ce mode d'emploi ne tarda pas à me signaler des inconvénients qui ont dû me faire renoncer à cette disposition ; le bain de verre se tassait sur elle-même, et l'introduction de la poussière, se faisant par des interstices, ne tardait pas à la salir. J'ai alors eu recours à cet inconvénient en construisant des lanternes dont les parois sont composées de tubes de 4 à 5 centièmes de diamètre, tubes dans lesquels la laine se place très facilement, et qui, obturés des deux bouts, ne laissent aucune issue à la poussière. La laine une fois mise placée, conserve sa position première et remplit toutes les conditions désirées.

Les avantages de mon procédé sont nombreux ; ils présentent une économie de lumière de plus de 30 pour 100 sur les globes opaques employés ordinairement. L'opacité peut être variée à volonté, puisqu'elle dépend de la quantité de matière introduite, quantité qui peut varier selon les cas. On peut, en colorant les tubes en toute nuance, modifier, absorber à volonté les rayons nuisibles de la lumière électrique. La disposition est en outre très économique.

Vous avez dû tenir des expériences faites par mes procédés, et j'ai pensé qu'il pourrait vous être agréable d'avoir quelques détails, auxquels je joins des photographies de ma lanterne. Cette photographie (voir la gravure ci-dessus) représente une lanterne très élevée, parce qu'elle doit être appliquée aux brûleurs Siemens, qui se placent au haut de l'appareil, au-dessus de l'arc voltaïque. Je n'ai pas besoin de vous dire qu'elle peut être modifiée et adaptée à tous les systèmes producteurs de l'électricité.

Recevez, etc.

L. CLÉMANDOT.

Alternative Electric Light Experiments.

We learn from the *Paper World*, published at Holyoke, Mass., that Mr. H. C. Spaulding, of Boston, who was at first going to put his plans into effect in that city, has gone to Holyoke on account of the cheap power, and has made arrangements with the Water Power Company to put a wheel into their new pit expressly for his use. To make the experiment which he will attempt will require 150 horse power, enough to run a paper mill. A tower about 175 feet high will be built and surmounted by an immense lantern of such power, says the enthusiastic editor, as to put all former electric lights completely into the shade. Mr. Spaulding will put up this tower and apparatus at his own expense, but he hopes to succeed so well that the city will adopt his system. His idea is that by filling the atmosphere above the city with light from several such electric towers he will get the same effect that we do from the sun and its reflected light, and that the shadows will be no darker than those made by the sun. His idea is to fill the stratum of atmosphere just above the city so completely with light that it will permeate spaces which no direct rays reach, just as the sun's light does immediately after the sun has set.

The light which he expects to throw out from one lantern will be equal to 300,000 candles, while the largest electric light yet attempted by any one else has been of but 10,000 candle power. The estimated cost of the apparatus is $15,000, irrespective of any investment for power, but after the system is once in operation the cost of running it, aside from the power, will be small. —*Sci. Am.*

The electric lighting of some portions of the South Kensington Museum during the past few days by way of experiment has been made with it in 160 Swan and in One Hundred Lilmer does not appear to have been very successful. Wilde's machine and lights were tried in the Asphalt Gallery and in one of the Shoeshanks Rooms; and the noise emitted by the lamps was very objectionable, and they had to be discontinued on that account. The Werdermann lamp was the one selected for trial in the Library, worked by a Gramme and afterwards by a Siemens machine, the motive power in each case being a gas-engine; but the results were not satisfactory to Mr. Werdermann, and he therefore suspended the trials until he could get a better arrangement for producing the current. The Werdermann light gave every satisfaction as regards steadiness and colour, but the expense of working, including carbons, was about three times as much as the cost of the gas lighting previously employed. It is said, however—but with what reason we know not—that in the reading-room the cost of gas will be much greater, while

Since Communicated to Patent Office

OUGHT FROM JERSEY.

Mr. Edison was recently called to the fact that New Jersey's great investor is seeking a site on which to locate one of the largest manufacturing establishments in the country. Several localities are offering inducements to him in choosing a place. Dr. Edison will take into consideration the facilities for shipping to all parts of the world, and the probability of securing all the workmen at home—that is, without going to adjacent neighborhoods, as it is desirable to have the employes at all times within easy call. We are told that the number to whom employment will be given will range from 500 to 2,000. Not only the home market but the European will must be supplied from the new factory, the investor having reserved to himself the exclusive right to manufacture the lamps recently patented by him.

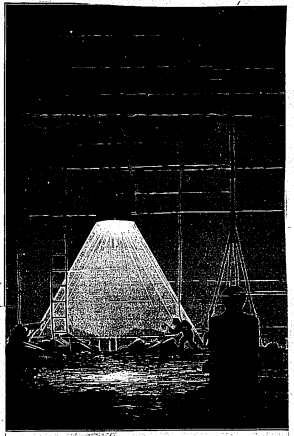
The question for our people to determine is, whether it would be to our interest to at least make an effort to include Dr. Edison to locate his works within our city limits. Our city certainly possesses all the advantages the great investor requires. Even now in his little settlement at Menlo he gives employment to more than a hundred people, but none of these have to find homes elsewhere. The city of Elizabeth is anxious to secure the prize, but we are confident the preference would be given our town if we would show a more liberal spirit. There are several excellent sites near the railroad and canal which would no doubt answer for the purpose. And then it should be remembered that our steamboat company furnishes a cheap and safe means of reaching the New York market, an advantage which manufacturers well understand.

SUBMARINE OBSERVATORY AND ELECTRIC LIGHT.

The accompanying engraving, taken from the *Leipziger Illustrirte Zeitung*, illustrates Bazin's submarine observatory and electric light, which has been found to be of the greatest service in examining wrecks, submarine foundations, etc. It was used for the first time in examining the wreck of the Confederate steamer Alabama, which was sunk off the French coast at Cherbourg. The electric light is contained in a heavy cylinder, about 6½ feet high and about 4 feet in diameter, and provided with a heavy plate glass bottom. The lower part of the cylinder contains alum water to counteract the pressure of the sea water, which increases very rapidly as the apparatus is lowered. The upper part of the cylinder contains a powerful electric lamp, the light rays of which pass through the alum water and the plate glass bottom, and lights up the bottom of the sea for a space about 100 feet in diameter.

Bazin's observatory, shown in the right hand corner of the engraving, is about 9 feet high and 2 feet in diameter. It is provided with two bull's-eye windows through which the person in the observatory can watch the divers that are at work on the wreck. As the water is an excellent conductor of sound the superintendent can converse with the divers very conveniently.

A person can remain in this observatory for about three quarters of an hour, and if any parts should break or leak he can enter the upper helmet and remain in the same from eight to ten minutes, thus allowing ample time to raise the entire apparatus to the surface.



SUBMARINE OBSERVATORY AND ELECTRIC LIGHT.

Electric Light.

We have not recently said much in regard to this subject in our columns, for the reason that for a considerable time very little that is new, or calculated to be new, has been brought to the public notice. Notwithstanding this fact, we are in position to affirm that much activity prevails among inventors of this class of devices.

Although there is an apparent pause in the advance of electric lighting, it is not to be denied that it has already made very substantial progress. The Fuller Electrical Company in Brooklyn is, we are told, working its manufactory to the very utmost of its capacity in the manufacture of lamps, dynamo-electric machines and other appliances for electric lighting. This is, we believe, the present state of affairs in nearly all establishments of this class.

A new machine has been invented by a Newark, N. J., inventor, from which we have heard very glowing reports. We have not as yet seen the machine in operation.

A very large increase in the use of electric lighting has been made this season at the American watering-places. By the aid of these lights bathing is continued during the evening as well as the day-time, wherever the state of the tide permits. The bathing establishments have found their incomes substantially increased by the employment of this new system of illumination.

Abroad, the Jablochkoff candle appears to have reached the highest success. A new electric lamp has been produced by M. Jamin. The Brush light, well known in this country, has been introduced into England, and its use is rapidly extending there.

The Jamin lamp is described as consisting of three electric candles placed side by side, each candle being formed of two parallel pencils, placed in vertical position, and burning from the bottom upwards. The candles are covered by very fine copper wire, which conducts the electric current, and is so arranged that the arc is maintained at the lower end of the pencils. When one candle is burned out, the next is automatically lighted. Each candle is stated to last two hours, and the cost of carbon consumed is about one cent per hour. The Gramme machine, consuming eight horse power and running at 1,500 revolutions per minute, supplies twelve Jamin lights, each of thirty-two candle power.

The Jablochkoff system has been now in use for eighteen months by the Metropolitan Board of Works in London for illuminating the Thames embankment, and it has not missed a single night. This is considered a remarkable success. A twenty horse power engine has sustained as many as eighty of these lights between Blackfriars and Westminster, a distance of over two and a half miles. Only fifty lights are, however, actually used. The expense of this light has been greatly reduced, and a contract has been made for the next twelve months at the rate of five cents per hour for each light, the illuminating power of which is guaranteed to be equal to that of three hundred and seventy-eight sperm candles. The glass globes used with these lights reduce the above named illuminating power to that of two hundred and sixty-five sperm candles. These lights are employed for a period of six hours each night, but this can be extended to eight hours, if desired. The difficulties at first met with in the use of the Jablochkoff light appear to have been entirely surmounted. Large companies are forming in different parts of the world to introduce it, the most notable of which is, perhaps, a Russian Company with a capital of four million dollars.

The Wenderamun light has had its capacity greatly increased by the recent improvements in the Gramme machine. It is capable of greater subdivision than any other known electric light, and is coming into considerable use in Paris for domestic purposes, the supply of electricity being generated at a central point, from which wires lead to the different localities where the light is required. This light produces an illuminating power equal to three hundred sperm candles by the use of only one-half horse power. Thirty lights, equivalent in power to three hundred sperm candles, are maintained by a twelve horse power engine.

It will thus be seen that in the question of economy, as compared with ordinary illuminating materials, a very great advance has been made; not so much in the introduction of new devices, as by a more skillful application of those already known.

The Edison light, which made so great a stir in this country a short time ago, has ceased to be much talked about. The opinion generally prevails that Mr. Edison has failed in his attempts to make any marked improvement in this field.

98

EXTENSIVE ELECTRIC LIGHT EXPERIMENTS.—We learn from the *Paper World*, published at Holyoke, Mass., that Mr. H. C. Spaulding, of Boston, who was at first going to put his plant into effect in that city, has gone to Holyoke, especially on account of the cheap power, and has made arrangements with the Water Power Company to put a plant into effect over all expenses for the season. He make the experiment, which he will attempt, will require 450 horse power, enough to run a paper mill. A tower about — 175 feet high will be built and surmounted by an immense lantern of such power, says the enthusiastic editor, as to put all former electric lights completely into the shade. Mr. Spaulding will put up this tower and apparatus at his own expense, but he hopes to succeed so well that the city will adopt the system. His idea is that by lighting the atmosphere above the city with light from several such electric towers he will get the same effect that we do from the sun and its reflected light, and that all shadows will be no darker than are those made by the sun. His idea is to fill the stratum of atmosphere above the city so completely with light that it will penetrate spaces which no direct rays reach, just as the sun's light does overhead after the sun has left us. The light which he expects to throw out from one lantern will be equal to 200,000 candles, while the largest electric light yet attempted by any one else has been of but 10,000 candle-power. The estimated cost of the apparatus is 15,000 dols., irrespective of any investment for power, but after the system is once in operation the cost of running it, aside from the power, will be small. The expense of lighting Holyoke at present, public and private, is estimated at 100,000 dols. a year, and for about this amount the seven towers which are proposed could be set up and the lights put into operation.—*Scientific American.*

It is not likely that the suggestion for lighting Chestnut street by electricity will be adopted at once, but it is worth while to consider the subject. There can be no doubt that electricity will supersede gas for general illumination, especially in the open air, and that before many years. Perhaps about the time that the Gas Trust expires by limitation and the gas works revert to the control of the city the use of gas will begin to diminish; but, however that may be, the city ought to have the best as well as the most convenient street lights that science can supply. Chestnut street now is very badly lighted; it hardly can be said to be lighted at all, except where private enterprise has furnished it the means, and the only square in which the illumination is at all satisfactory is that between Eighth and Ninth streets, which is well lighted by two electric lamps, one at each end of the square. We should say that one lamp at the centre hung over the centre of the streets at each intersection would do the work now feebly attempted by a dozen sickly gas lamps, and it is probable that the cost would not be greater. There are a great many details, however, that would have to be considered, and we should need to consult the experience of foreign cities, where the subject has already received a good deal of attention. Mr. King's resolution will lead to a profitable public inquiry, and the matter certainly is worthy of a careful report.

Progress of the Electric Light Abroad.

The fact that much more publicity is given in England and on the Continent than here to the results attained by the promoters of the electric light has given rise to the impression idea that little is being done here. Such is not the case, however. The applications of the light to the illumination, not alone of large spaces and of places of amusement, but also of factories and mills, are becoming more numerous. It is even rumored that Edison, of whom the public has lost sight entirely, has nearly completed works to test his light on a large scale in this city. The development in this country is steady and encouraging, because it is divested of all attempts to catch public attention by sensational reports.

Abroad inventors are active and capitalists confident. The *Times* announces progress there in an able manner, but falls into the error of underrating the strength of the movement here. M. Gramme, who has done so much to aid the progress of electric lighting, is adapting his well-known dynamo-electric machines to the requirements of the Jablochkoff, the Werdermann, the Dagieff, and other forms of the light. M. Jamin has come forward with a new light, and the Siemens light is said to be more than maintaining its reputation. The Brush light has been introduced into England from this country, and its use is extending. The Jamin light consists of three candles placed side by side, each candle being formed by two parallel carbon pencils held in a vertical position, so as to burn from the bottom. A bank of fine copper wire surrounds the candle and conducts the electric current, and is so arranged that the luminous arc is always kept at the lower end of the pencils. When one candle is burned out the next is kindled automatically. Each candle burns two hours, and the cost of the carbon consumed is but a trifle over a cent an hour. A single lamp would thus burn six hours without requiring any attention, at an expense of not more than 7 cents for material consumed, to which, of course, must be added the cost of generating the current. A Gramme machine, driven by an 8-horse engine at the rate of 1500 revolutions per minute, sustained twelve Jamin lights, each equal to thirty-two candles. It was found that with a machine making 1500 revolutions per minute, and a wire 1-20th of an inch in diameter, six lights could be sustained on a circuit of five-eighths of a mile. By doubling the size of the wire and increasing the revolutions to 2000 per minute, a circuit of ten miles can be operated. This light is in the hands of a French company with a capital of 8,000,000 francs, and one of its founders and directors is a man who is proprietor of about sixty gas works.

The most conspicuous success thus far has been won by the Jablochkoff system. For eighteen months the Societe Generale d'Electricite, in connection with the Metropolitan Board of Works, have maintained the light on the Thames Embankment without missing a single night. The light was recently suspended for a few days for the purpose of cleaning the engines which has been resumed. It was found that a single 25-horse power engine under the Charing Cross bridge could maintain as many as 80 lights between Blackfriars and Westminster, something over 2½ miles. The number of lights in actual use, however, is but 50, extending the whole length of the Victoria Embankment.

Experiments undertaken with a view to reducing the expense of this light have been attended with very gratifying results. The terms of the contract for the next twelve months are at the rate of 5 cents per hour for each light, and the illuminating power of each is equal to 378 sperm candles, but this is reduced by the general glare from 252. The lights burn about 4 hours, but can be burned eight.

The Jablochkoff light has been successfully used for long distances, and on a large scale, the Paris Salon having been lighted by it with 400 lights for two months. A Russian company has been formed, with a capital of $4,000,000, to perfect and apply this system.

A steam engine is being erected in the South Kensington Museum for use in connection with the Brush light. A large court, formerly lighted by 1700 gas jets, is now lighted by eight Brush lights, at a cost of 10d. per hour, a saving of 10s. per hour as compared with gas at the London price of 80 cents per thousand feet. Here, as well as at the British Museum, the great advantage of the electric light over gas consists in the fact that it perfectly harmless and void of danger, while the combustion of gas is destructive to paintings, decorative work, and book bindings. In a large biscuit factory at Bermondsey the light is found to possess the positive advantageage of enabling the workmen to distinguish the most delicate shades of color, a matter of necessity in that business. Brush's brewery is to have the Brush light, and the company are about to erect works in the heart of London, intending to supply the light from a central point over a circuit 10 miles wide.

The Siemens light has been permanently adopted at the British Museum, and is in use on a large scale at the Victoria Docks. The improvements recently made in the Gramme machine have increased the power of the Werdermann light, and its capability of subdivision—in which respect it is said to surpass all other lights—has led to its application to domestic uses on a considerable scale in Paris. The supply of electricity is generated at a central point, and the light is held on by wires wherever required with as much ease as gas. A Werdermann light equal to 300 candles requires the use of only one-half horse power, and a 12-horse power engine will maintain 30 lights, each equal to 300 candles. A notable feature in the progress made by all these lights is in the reduction of operating expenses.

In conclusion, we may add that for therapeutic gas compounds the electric light is losing much of its terrors, not because of a conviction that its competition need not be feared, but because gas manufacturers are becoming sufficiently alive to the fact that there is ample room both for the electric light and for gas. "*M. Jamin has made efforts to convince a number of representatives of the gas interest at Paris of the absence of any danger to its future growth and prosperity.* From the language of one of their number, M. Jordan, it appears that they are beginning to take this view.—*Iron Age.*

THE MAGNET.

One of the difficulties experienced in bringing the electric light into use is the finding of a suitable shade or globe, which, while diffusing the light, will not absorb more than a slight per centage of the illuminating power. The opal and ground glass globes, with which we have become familiar, absorb from 20 to 50 per cent. of the light produced by the electric arc—a serious loss, which has been tolerated in order to obtain the necessary diffusiveness. M. Clemendot claims to have hit upon a method which supplies the diffusive power with the minimum of loss. He takes his lantern of a number of tubes of clear glass, united at the sides. These are filled with glass wool, which is given in a state of extremely fine threads. The surfaces of these threads reflect the light in all directions, and the tubes, being clear, the absorption of light is reduced to 15 per cent. The opacity can, however, be increased by putting a larger quantity of the glass wool into the tubes, and, what is perhaps more important still, as the new lamp entirely removes the objection to the "lineness" of the light, for either the tubes or the glass wool can be stained so as to yield light of any desired color. //

Sept 15, 1880 //

THE MAGNET.

Before the American Association for the Advancement of Science, on the 31st ult., Mr. E. B. Elliott, of Washington, read a paper on electric lighting, applied to large spaces. He instituted a comparison between the relative cost of the lighting of large areas by illuminating gas and by electric processes, deciding in favor of the latter. He then compared the relative efficiency of the several processes of electric lighting, showing the greater economy of the Jablochkoff candle and of Wilde, the electric arc processes being, in the lighting of large areas, by far the most economical, and the former for the purposes mentioned beyond question. The electric arc and the incandescent processes, however, are not to be considered in the light of rivals, the former being specially adapted for lighting of large areas, while the latter, so far as successful, is designed for interiors, as for domestic and like purposes. He then treated the relative economy of large and small electric lights, showing that the economy of large electric light greatly transcends that of small ones. He discussed the mutual action of electric currents, a knowledge of the law of which has at the very foundation of a mastery of the subject of electric lighting.

THE MAGNET.

A PERSON asks contemptuously in the *Morning Post*, "What has women invented," to which "A Man" replies: "Well, women did not invent herself, the creation of her was reserved for the greatest inventor of all, and she is the most beautiful invention of costly and intricate machinery and mysterious powers, known or unknown. Less fastidious may, but, while man has been doing these things, she has invented the happy home wherein he can rest after his toil, invented the spirit of cheerfulness in that home, a desire to help him over all the rough spots of life; and when worn out with sickness and pain, she has invented that wonderful magic of a woman's touch whereby our pains are relieved, and we are led to bless the day when mankind was given that wonderful and blessed invention, woman." //

INTERESTING TELEGRAPHIC ITEMS.

The pneumatic tube system of letter telegrams in Paris now operates fifty miles of piping, from six central stations, where motive power is produced by steam-engines of 153 horse-power. About 400,000 dispatches are sent per month, the average charge being less than ten cents.

Sept 15, 1880

SCIENTIFIC NOTES.

M. THOUVE has been exhibiting his electrical polyscope at the annual meeting of the Physical Society of Paris. It was placed in the stomach of a fish, which suffered no inconvenience, and the electric light rendered its body semi-transparent.

It is well known that if a long dry tube, open at both ends, be held over a jet of burning hydrogen, a musical sound is produced, the pitch and quality of which vary with the length, thickness, and diameter of the tube. It has been proposed to adapt such a tube to a safety lamp underground, in mines, and to place it near a telephone in communication with another in the manager's office on the surface. The alteration of the sound due to a greater or less admixture of gases with the air of the mine would warn the manager of the state of the atmosphere in the working.

EDISON'S "PERFECT LAMP" PERFECTED.

(FROM OUR AMERICAN CORRESPONDENT.) Aug 31 1878

Another forecast in the matter of electric lighting has been made public, to the effect that Edison has "perfected his perfect lamp" and that he is now about to proceed to secure the actual lighting of New York—or rather a portion of it, "after a) experiment—with his new lamp. Further, he claims that he can furnish the electricity for lighting and supplying electric power less than one-fifth the cost of that used in the light way, and thus at once consign gas companies to the things of the past, to rest upon the shelf in company with the linkboy's torch. Of course we have lately been canvassing the lower business portion of New York, with the object of ascertaining whether the overplussed and citizens would agree to the adoption of motive power and lighting purposes, if Edison were to establish the central station, and the matter seems to be very well settled with the result of the canvass, and satisfactorily, that a sufficient number of persons have pledged themselves to use his system as to warrant the erection of suitable works, and thus the necessary data can be secured. Edison's experiments have been carried on with great secrecy, even, if saving to the gas companies the knowledge of what he is doing, it should be termed to supply electricity for lighting purposes at cost to the people.

When such statements as these appear in the daily papers on your side of the Atlantic, as they sometimes will, you are apt—I should say gas engineers—are very apt to take alarm. I therefore take this early opportunity of writing to put before your readers an account of the so-called invention of Mr. Edison's lamp, which are exciting so much comment here, and I will not be surprised to see how much cause there is for any uneasiness on the part of gas engineers.

The improvements in the lamp are three in number. First, the brancelled, only needed for conducting the carbon incandescence in vacuo of glass, while the "perfect lamp" may clear; second, the globe is a little more than the diameter apart, third, the carbon of the horseshoe is sure of the same thickness as within. Let us consider these in the order named.

First. As to the necessity of a vacuum, or incandescence in vacuo, when compared with a gas flame, and consequently more dazzling to the eye, the light may be a little more trying to the eyes of those who look upon it—to the beholder when it is enclosed in a gas globe. On the contrary, the round glass will discount more light than the clear globe, and thus reduce the light to a degree, at least similar to that of the gas flame. Further the light is more "mellow," whereas the loss of light caused by a ground globe is usually placed at about 15 per cent., the inventor claims two reasons to account for this discrepancy. First, that the electric light being a pure white light the rays therefrom will pass through a ground glass globe in a more truthful tone, while the globe would greatly modify the yellow light), and, secondly, that the heat radiated by a gas flame is so much greater than that from the electric light, that the globe, being of a much smaller area—the light is concentrated by a smaller globe being so small—of reason, it must certainly so be. Now in regard to the first it before it leaves my sight this evening, when one of the great drawbacks to the use of large electric lights has been the necessity of constantly renewing the carbon points, or globes, and the consequent stoppage of the light during such renewal, and that owing to this fact much lighting power is lost. Of the second improvement, as to how that loss of the vacuum globe would also accounts for the diminished heat, I would ask, if the larger area of a gas flame is the larger amount of heat generated, and if the light obtained, the difference between the size of Edison's new globe and the ordinary gas globe is not sufficient to account for the loss of heat, for gas globes were 8 inches in diameter. Besides there is another thing to be noted in comparing the ground glass globe with the clear globe. In the former instance all the light has to pass through the globe, while in the latter case a good deal of the light which is reproduced by the globe, passes through the lamp itself, and thus the light is not lost. Again, the ground glass globe, a great gain, the light globe will be increased in power—as of great service.

The third improvement is of some value, if it does what the inventor claims for it, viz., that the carbon will not burn away. It will be remembered that in the carbons before forming the loop was of greater breadth than thickness, so the light was not lessened as the carbon burned away, but it was better to be forming a regular electricity for carbons have never stood to what figures the purveyors of the electric will not consume more than about a quarter of a mile square, but I suppose to chiefly with office-buildings, hotels, and the like. In the former instance the buildings stand, it used to run passenger-elevator engines and other various kinds of work, but chiefly for lighting purposes. The latter is chiefly with office-buildings, hotels, and the like. In the former instance the buildings stand, it used to run passenger-elevator engines and other various kinds of work, but chiefly for lighting purposes. The latter is chiefly with office-buildings, hotels, and the like. In the former instance the buildings stand, it used to run passenger-elevator engines and other various kinds of work, but chiefly for lighting purposes. So I do not think the new move will meet with a great deal of success, even if the attempt is made. However, the inventor's plans, as before intimated, is to supply the motive power, and the light, by the 16-candle lamps, and give the light as a part of the rent. It is stated that almost all the light used in the section—except that burned in the houses of which he makes no mention—is that used in the daytime, by dark editors, &c., as he would have to provide the power, to supply the engines of 50 horse power.

Of course all figures connected with the Menlo Park are almost valueless for purposes of comparison, as they are not to be taken alone. The smaller power of the new lamps is placed at 16 candles, an improvement, according to the inventor's own figures, of 4 candles in the new lamps. Edison's estimates for running the same will be sold at 25 cents. Edison's [illegible] will last with ordinary care about six months. The number of lamps mentioned per horse-power is given as 8, the plant necessary to supply 800 lights being as follows:—

	Dols.	C.
100 horse power engine with one large generator . . .	4000	00
Boiler, &c., &c.	1600	320
Total	5600	1120

The gas plant necessary to supply 800 lights is placed at from 7000 to 10,000 dols., and buildings are presumably left out in either case, while the cost of maintaining the gas plant is to the consumer—or perhaps better users—provides are to be offset by the gas companies meter.

In fact, Edison claims that where a gas company would spend 1,50.74 cents (Rs 2125), a gas company would have to pay 2 dols. (Rs.) Now had the inventor did not stretch it a cent, and make the former figure 1 dol. 72 cents?). Manifestly the cost of his plant is too low. I doubt very much that the plant mentioned could be procured for the amount mentioned. It is unnecessary to look to its author, as the apparatus would have to be in duplicate—amounting to 11,200 dols. (22,240), which, when compared with the inventor's highest estimate of 5600 dols., leaves a loss of 5600 dols. (11200). Then, does not show a very great saving in favour of the price of his plant. A little further consideration will show how much larger the capital of an electric lighting company must be over a gas company's, more even than intimated in the foregoing figures, because while the gas company will need to have works scattered all over the city, in many cases having two or three on different sides, the electric company can build where land is cheap, and at a distance from the centre of business, and thus save the enormous cost of gas-mains, as they would have to be of large size, and, of course, entered in pairs.

But it is a waste of time to attempt to form any comparison between which system of lighting would the cost of gas; and it is necessary, as the public at large are interested in the matter, that a public test should be made, or however great the saving effected by the electric light, however unsightly fixtures can possibly do with its light, that consumers are slow to lose. For, even where the electrical apparatus is to be had, the accident should occur in the machinery the lights would probably go out before the extra engine could be brought into action, which with gas there would be no danger. Then, again, as that if anything goes wrong in the works the light would be maintained. Again, as Edison proposes to make his profit from supplying the electricity, he would naturally run his conductors only where he could get a large number of customers for his engine; consequently it would only be a limited portion of each city where he could at all interfere with gas companies.

In truth the his latest move shows the utter weakness of his case; and here, fortunately, I take, as a matter of existing the price of the Edison Company's stock, or gas as a preparatory step to giving up all intentions of introducing his system in this city, and I am sorry for the gentleman. He is certainly very enthusiastic as to what is now accomplished in revolutionizing the railway system, through the supplanting of steam motive power by the introduction of his electrical engines; but it does not seem within my province to enter into details on this head, suffice it to say, I am sorry that locomotives will be placed aside, like gas companies, in a very few years.

THE ELECTRICIAN.

Electric Lighting at Glasgow.—The Exhibition of Gas and Electric Lighting Apparatus at Glasgow will be opened on September 28th, and continue till October 26th. Sir William Thomson's name appears on the list as a vice-chairman. Besides the manufacture of coal gas, oils, and candles, there will be a section devoted to electricity, its generation, and application to purposes of lighting, heating, telegraphy, and motive power, &c. Photometric apparatus for indicators, illuminated buoys, and many other miscellaneous articles will be displayed. It is to be hoped that makers of electric lighting apparatus will seize the occasion and make a good show of their productions. A side by side comparison of this kind is the best answer to the carping criticism of gas supporters on the merits of electric lights.

The Electric Light in Brussels.—The national *fête* at Brussels has been the occasion of a fine display of electric lighting in the Belgian capital. There are many boulevards and buildings in the little Paris permanently lighted with Jablochkoff's candles; but on the night of the special illuminations many thousand lamps were blazing. The magnificient theatre, which is believed to be the largest in the world, was splendid with the brilliant globes, and the front of the Gare du Nord in particular presented an enchanting spectacle. All the outlines of the architecture were picked out with ordinary gas jets, and between these on the windows, doors, and arches were placed a great number of globes of various colours enclosing electric candles. These paint-coloured globes, some green like emeralds, others deep red like rubies, and some of sapphire blue, glowed like Aladdin's gems, and made a rich effect. Even in Belgium fairs the enterprising mountebanks and hucksters-have adopted the electric light in preference to the naphtha vreuset. Is not this enough to make the Billingsgate fishmongers blush?

The Electric Light at the South Kensington Museum.—Major Russell, R.E., who is entrusted with the charge of the buildings of the South Kensington Museum, gives the following account of the experiments of last year with the electric light:—Arrangements were made in the early part of the year with the British Electric Lighting Company for trying a Wilde's machine and lights in the Raphael Gallery and one of the Sheepshanks rooms. The machine was worked by the gas engine purchased in the preceding year. The trials, however, were discontinued after a short time, on account of the buzzing noise emitted by the lamps, which was found to be very objectionable. The promotors expected to be able to overcome this difficulty, and it was intended to have some further trials when this should have been done; but before long the company was wound up,

---

Lamps for the Electric Light.—M. L. Cimandot suggests the use of spun glass as an effective method of securing the diffusion of the light. He would surround with double glass globe, between which is placed the spun glass. Experiments have been successfully made at large warehouses of the Louvre at Paris.

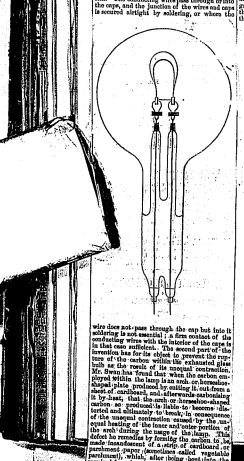
---

and no further trials were made. It was found from the trials that two lamps lighted one of the Sheepshanks rooms, in which the consumption of gas is 600 feet per hour; and that six lamps gave sufficient light for the Raphael Gallery, usually lighted by a consumption of 1,800 feet of gas per hour. Apart from the noise, the light was generally satisfactory, though the lamps required rather better adjustment to make them burn satisfactorily, and to enable six of them to be properly worked by the gas engine. This better adjustment could no doubt have been effected with care, but it was not thought advisable to continue the trials with this view as long as the great defect of the noise remained. As regards cost, the motive power and carbons for this light were found to cost 2s. 6d. an hour for the Raphael Gallery, against a cost of 6s. 6d. an hour for gas. No determination of the probable cost of wear and tear of the machinery, &c., could of course be arrived at from these limited trials, but the saving of 3s. 10d. an hour, or nearly £140 a year, would certainly be ample to cover this cost, as well as the interest on the outlay for the machinery. At a later period Mr. Werderman, the inventor of another form of electric lamp, lent some of his lamps for trial to the Art Library. They were worked by a Gramme machine hired for the occasion, and afterwards by the Siemens machine, the motive power in each case being the gas engine. Neither of these machines however, gave results satisfactory to Mr. Werderman, and at his request the trials were discontinued until he could get a machine made which he believed would answer his purpose better. He has not, however, resumed the trials as yet. The Reading Room was satisfactorily lighted by these lamps. The light was steady and of good colour, and the amount of heat given out by them being imperceptible, there was a favourable contrast to the gas lighting, which makes the room very hot. There were no signs of the evolution of any noxious vapours, but this is a point which will require further investigation. Eight of these lamps were used in the Art Library, but the best results were obtained when seven only were used at one time. They were placed at the same height above the tables, about five feet, as the gas lights, and the consumption of gas in the lights which they replaced is at the rate of about 6d. an hour. The gas consumed in the gas engine which worked the electric lights cost about 10d. an hour, and the carbons about 8d., so that these two items alone cost three times as much as the gas lighting. It must be remembered, however, that in the new Reading Room, which will be nearly 25 feet high, it will be necessary to have the gas lights more than five times as far above the readers' tables as they are in the present room. The consumption of gas in proportion to the number of readers will therefore be largely increased; but there will be no corresponding increase in the number of electric lamps, which may be as near to the tables as they were in the above-mentioned trials, and therefore the cost of gas, and of even the Werderman electric light will not be much greater than that of gas in this case, and in every other point the advantages will be with the electric light. Mr. Redman Green 9,224,000 cubic feet of gas were consumed, costing £941 10s. 1d.

English Mechanic Sept 10 1880

SWAN'S ELECTRIC LAMP.

THE annexed engraving we illustrate one of the electric lamps patented by Mr. Swan, of Newcastle-on-Tyne. It is a first view of his multiple carbon lamp, in which there are five lamps rendered incandescent by the passage of the current; but in the ordinary lamp there is only one carbon filend. The invention, it will be seen, resembles Edison's in principle, but the first part of Mr. Swan's has for its object the prevention of the cracking and leakage of the glass bulb or globe usually caused in consequence of the heating of the carbon filament or conducting wire, which when strongly heated melts the glass globe, causes it to crack and leak at or near the junction of the wires and glass. The means used is the employment of a pair or cups of platinum as an attachment to the lamp globe, or a tube proceeding from it at the place where the conducting wires enter the lamp inclosure. Each cup is attached by the fusion of the glass around its rim. The conducting wires pass through or into the cups, and the junction of the wires and cups is secured airtight by soldering, or when the



latticures, or an alloy of platinum and tellurm attached to the conducting wires, which pass through or into the cups. The third part of the invention has for its object the prevention of the evolution of gas occluded by the conducting wires within the lamp. Mr. Swan accomplishes that by coating the conducting wires within the lamp with glass or enamel. Mr. Swan claims as his invention the use of cups of platinum fixed to the glass of the lamps as a means of preventing the cracking of the glass by the heating of the conducting wires. Second, forming carbons for incandescent lamps, that is to the manner described, in which a strip of paper or card bent to the required form is carbonized by heat, and then it is held in a vessel containing charcoal or other form of carbon in powder. Third, forming the carbon for incandescent electric lamps by carbonising vegetable parchment of the required form, in the manner described. Fourth, employing several carbon anthes in each lamp, as described. Fifth, preventing the evolution of gas occluded by the conducting wires within the lamp, by coating the conducting wires within the lamp with glass or enamel.

Patentee Swan Sept 1 1880

IMPROVEMENTS IN THE PRODUCTION OF THE ELECTRIC LIGHT.

By F. H. VARLEY.

THE author describes how he has divided the electric light. In place of carbon points he uses tinuous columns of finely powdered graphite or carbon, continually renewed. One method—this powder falls from a platinum or iridium funnel like the sand in a sand-glass. The electricity passing in the direction of the falling particles. The falling stream of carbon is in a closed vessel in a vacuum or in carbonic acid atmosphere. By altering the carbon dust with lamp black, gravel, etc., the resistance may be varied. In production of the current an arrangement which seems somewhat like a Heimsholt's coil is employed. He also describes the use of a battery to work a magneto machine to drive a Holtz machine, and from this the supply of electricity is obtained.—*Society of Arts Journal*, Electrical Number.

Abstract of a paper read before the Royal Society of Edinburgh by James Blyth, M.A., F.R.S., on May 3 1880.

IRON Sept 10 1880.

THE JAMIN ELECTRIC LIGHT.

THE Jamin system of electric lighting, particulars of which have already been given by us, was recent meeting of the British Association at Swansea, by the Comptoire Générale d'Eclairage Electrique of Paris. In the pavilion in which the exhibition and soirees were held, and which is 180 feet long by 140 feet wide, were eighteen lamps suspended from the roof. These lamps were mounted in three different circuits of six lights each, and six more lamps, mounted in a fourth circuit, were distributed as follows:—Two lamps at Mr. Glenge Heand's saw yards, situated at a distance of about 200 yards from the pavilion; two lamps on the walls where the various appliances used in connection with the Jamin's system, and the lamp itself, were exhibited and demonstrated by Mr. J. A. Berly, C.E., the representative and engineer in the country of the Compagnie Générale d'Eclairage Electrique, and under whose immediate superintendence the whole of the plant for electric lighting was erected and fixed; one lamp over the principal entrance, and two lamps inside the pavilion, lighting the approaches leading to the main entrance. The electricity for the current was raised by two self-exciting Gramme dynamo-electric machines, capable of feeding from four to sixteen lights each, but arranged to feed twelve each. The Gramme machines were driven by the steam-engine of Mr. Heand's saw mill; and who kindly lent the steam-power for the occasion, and also the services of its foreman and staff. The engine is an horizontal single cylinder of 20 horse-power, and manufactured by Messrs. Charles Foote, of Millwall, London. The light attracted great attention and proved very successful as an illuminator.

Printed Telegram Sept 10 1880

Swan Electric Light for Light-Houses.

THE Light-House Board of the United States Light-House Board is valuable in containing some useful information respecting the comparative merits of the several forms of the electric light, and of the several appliances that have been devised for producing it. The report on this topic discusses, (1) the modes of producing electric illumination, (2) the instruments for producing electrical currents, and (3) the results of measurements of luminous intensity.

Respecting the first category, the report notices three modes of producing electric illumination; (a) by the electric arc, (b) by ignited conductors, and (c) by incandescent gases. Respecting the electric arc, the report commends upon several objections attending its use. It is unsteady; and the carbon poles wear away and are gradually consumed; and the point is made that while very ingenious regulators have been devised to overcome the troubles and inconveniences arising from these causes, they cannot control the accidental variations in the structure of the carbon poles, which causes them to wear away unequally, and by reason of which the arc shifts its position, giving rise to frequent and often considerable variations in the intensity of the light that it emits.

The report refers to certain observations on this point, from which it appears that variations in luminous intensity from this cause were noticed, within a few minutes, of from 400 to 2,000 candles. The remark, however, is appended, as a qualifying clause, that "since the great improvements recently made in the homogeneity of the carbon poles, and in the regulating machinery, and since the introduction of reflectors, the electric arc is no longer too unsteady for practical purposes."

On the production of the electric light from incandescent conductors, the report is decidedly unfavourable. It affirms that this method of producing electric illumination is open to the grave objections of great wastefulness of "energy (and consequent costliness) and the rapid destruction of the conductors by disintegration. A current, for example, that would furnish an electric arc of from 1,000 to 2,000 candle-power, would not generate a light of more than 50 to 100 candle-power with platinum wires, and the platinum soon becomes brittle and broke up. Better results were obtained with carbon rods placed in exhausted glass tubes, but the carbons soon disintegrated. The report is unfavorable to lamps of this class, and the fact is worthy of notice, that the experiments upon which the conclusions just stated were reached, antedate those of Mr. Edison which lately attracted so much attention.

Respecting the practicability of subdividing the electric current, which is one of the indispensable principles of any system of electric lighting adapted for domestic uses, the report gives some interesting and suggestive figures of the great loss of energy which such division necessitates. A current of given strength, for example, when concentrated on a single lamp, gave a light of 66 gas jets (of 16 candles each); when divided between two lamps, the light was reduced to 24 each; among three lamps, it gave 14 gas jets each; among four, 8 each; and among five, 4 each.

The report also describes and explains the action of 17 magneto-electric machines, and gives the results of a number of comparative tests of the economy and illuminating power of some of the best known of those machines and lamps.

GAS, CANDLE, AND ELECTRICITY.—It is not generally known that the first to find out the exceptional advantages of carbon cut from the retorts of a gasworks in producing the electric light was Mr. Golding Bird. In a letter to the *Philosophical Magazine* for January, 1838, describing his new induction coil, he expressly states that he gets the most brilliant sparks from electrodes of this material.

ELECTRICIAN, SEPTEMBER 11, 1880.

SWAN'S LAMP.—At the time Mr. Edison brought out his lamp, it was stated that Mr. Swan of Newcastle had long ago tried a similar plan, and found it a failure. He states, however, that he has now succeeded in devising a plan to keep the incandescent matter intact. It is to exhaust the containing vessel to a high degree, at the same time raising the carbon to as high or a higher temperature if possible than it is likely hereafter to be subjected. Whilst in this incandescent state the exhausted containing vessel is hermetically sealed. This operation is said to obviate the failure of the carbon by disintegration.

BURTON-ON-TRENT.—Messrs. Bass and Co. have introduced the electric light into their extensive premises at Burton-on-Trent. There are at present twenty-one lights, worked by a Brush dynamo-machine, the whole supplied by the Anglo-American Electric Light Company. The machine is driven by a 10 horse-power portable engine. Two rooms—the cask office and the square room—are fully lighted by electric lights, whilst other parts are only partially lighted. Hitherto the cask room has been lighted by thirty-five gas lights, and these are replaced by two electric lamps. Mr. Bass is reported to be fully satisfied with the experiment.

ELECTRICIAN, SEPTEMBER 11, 1880

ELECTRIC LAMPS.—Mr. Patrick Drew, of Brooklyn, has patented what he considers to be an improvement in the Edison lamp. He constructs his vacuum chamber and sealing tubes in such a manner that the tube is closed round the wire at the point best subject to expansion and contraction, and arranges that at the point of maximum expansion and contraction the wire is practically free without affecting the glass. Mr. Drew evidently does not understand the difficulties to be overcome before a vacuum lamp will become commercially possible. Let him devise a non-disintegrating material for the burner, and then perhaps his plans may be thoroughly considered.

Electric lighting has been having a trial along the harbor front of Montreal, and it is pronounced a success. The system in use is the Brush-dynamo electric machine, working a single circuit of 14,000 feet or 2½ miles in length, on which are arranged twenty-one lamps, any sixteen or lesser number of which may be used at once on such wharves as vessels desire to handle cargoes during the night, the remaining lamps being simply switched out as a pendulum may be turned off. The length of the district covered by the lamps is 1 1-32 miles, and the wharf frontage, including piers, is 9,100 lineal feet, or nearly one and three-fourth miles over which the light of the sixteen lamps may be distributed as desired.

Hitherto the cask room has been lighted by thirty-five gas lights, and these are replaced by two electric lamps. Mr. Bass is reported to be fully satisfied with the experiment. //

Gas and Water Notes.

ANSWERS TO CORRESPONDENTS.

C. A.—The price of the South Metropolitan Gas Company—p. per 1,000 cubic feet—is the interest on their debenture stock.

INQUIRER.—Messrs. Crosby, Lockwood, and Co., of Stationers' Hall-court, publish a work on Gas Meters.

The Jamin Electric Light.—This system of electric lighting, particulars of which have already been given in *The Metropolitan*, was exhibited for the first time in this country on the recent meeting of the British Association at Swansea, by the Compagnie Générale d'Eclairage Electriques of Paris, and, as was of course to be expected, much interest was evinced in the experiment. In the pavilion in which the exhibition not above were held, and which is also lit from top by 120 foot wide, eighteen lamps were suspended from the roof. These lamps were mounted in three different circuits of six lights each, and six more lamps, mounted in a fourth circuit, were distributed as follows:—Two lamps at a sawmills, situated at a distance of about 250 yards from the pavilion; two lamps on a mast, where the various appliances used in connection with the Jamin system, and the lamps itself, were exhibited and demonstrated by Mr. J. A. Berly, C.E., the representative of the company; the pavilion, lighting the approaches leading to the main entrance. The electric current was produced by two self-exciting Jamin dynamo-electric machines, capable of feeding from four to sixteen lights each, but running for twelve each. The Gramme machines were driven by the steam-engine at the saw-mills, the proprietor of which had kindly lent the steam-power for the occasion, as well as the use of his premises and staff. The engine employed was an horizontal single cylinder of 20-horse power, manufactured by Messrs. Charles Powis, of Millwall, London. Of the practical result of the trial we are not able to speak in very positive terms, not having been afforded an opportunity of judging at on the occasion, but we are assured by those who were, and whose opinions on such a subject we certainly consider worth having, that the success of the light as an illuminator was most decided. We are exceedingly pleased to hear that the exhibition proved so successful, and we trust that before long the metropolitan public will have an opportunity of judging for themselves of the merits and value of the system.

Electric Light.—If any one doubts the applicability of the electric light for trading purposes, let him visit the Coffee Palace Company's establishment under the Royal Exchange in the City, there he will see any day two or three hundred people dining, in what would otherwise be called a large vault, but properly decorated, and lighted by electricity, as as light as day, and perfectly free from heat or unpleasant smell.

Progress of the Electric Light Abroad.—The Mid-Kent Telephone Company has given its England and on the occasion there, how is the results attained by the promoters of the electric light, has given rise to the erroneous idea that little is being done here. Such is not the case, however. The applications of the light to the illumination of mines, to the spaces and of places of amusement, but also of factories and mills, are becoming more numerous. It is even rumored that Edison, of whom the public have lost sight entirely, has nearly completed work to test the light on a large scale in the city. The development in this country is steady and satisfactory, because it is divested of all attempts to catch public attention by sensational reports. Abroad inventors are active and industrious enough. The *Times* summarizes progress there in an able manner, but falls into the error of underrating the strength of the movement here. M. Gramme, who has done so much for all the progress of electric lighting, is adapting his well-known dynamo-electric machine to the requirements of the Jablochkoff, the Werdermann, the Rapieff and other forms of the light. M. Jamin has come forward with a new light, and the Edison light is said to be more than realizing its promises. The Brush light has been introduced into England from this country, and its use is extending. The Jamin light consists of three candles placed side by side, each candle like being 18 inches long. The carbon pencils held in a vertical position, so as to touch the bottom. A pair of fine copper wire surrounds the candle and conducts the electric current, and it is arranged that the junctions are always kept at the lower end of the pencils. When one candle is burned out, the next is kindled automatically. Each candle burns two hours, and the cost of the whole apparatus is but a trifle over a cent an hour. A single lamp would thus burn six hours without requiring any attention, at an expense of not more than seven cents for material consumed, to which, of course, must be added the cost of generating the current. A Gramme machine, driven by an eight-horse engine at the rate of 1,500 revolutions per minute, sustained 12 Jamin lights, each equal to 32 candles." It was found that with a machine making 1,200 revolutions per minute, and a wire one-twenty-sixth of an inch in diameter, the lights could be sustained on a circuit of five-eighths of a mile; by doubling the size of the wire and increasing the revolutions to 2,000 per minute, a circuit of 10 miles could be maintained with the same light. The Gramme is a French company with a capital of 8,000,000 francs, and the name of Gramme, the inventor is a man who is proprietor of about 60 gas works.

The employees exceeds than for has been won by the Brush machine during the 18 months for the Consolidated Electricite, in contract with the Metropolitan Board of Works, have maintained the lights on the Thames embankment without missing a night's light. The lighting was recently suspended for a few days for the purpose of cleaning the engine, which has been running. It was with a single horse-power engine under the Charing Cross bridge could maintain as many as 80 lights between Blackfriars and Westminster, something over 2½ miles. The number of lights in actual use, however, is but 50, extending the whole length of the Victoria Embankment. Experiments undertaken with a view to reducing the expenses of the light have been attended with very gratifying results. The terms of the contract for the next 15 months are at the rate of 5 cents per hour for each light. The actual power of each is equal to 978 sperm candles, but this is reduced by the ground glass globes to 750. The lights burn six hours, but can be burned eight. The Jablochkoff light has been successfully used for long distances and on a large scale, the Avenue Opéra having been lighted for 1½ mile with 400 lights for two months. Experiments have been made with Edison's system, and the results are highly satisfactory. The Edison light is said to be more than realizing its promises. The Brush light has been introduced into England from this country, and its use is extending. The Jamin light consists of three candles placed side by side, each candle like being 18 inches long. The carbon pencils held in a vertical position, so as to touch the bottom. A pair of fine copper wire surrounds the candle and conducts the electric current, and it is arranged that the junctions are always kept at the lower end of the pencils. When one candle is burned out, the next is kindled automatically. Each candle burns two hours, and the cost of the whole apparatus is but a trifle over a cent an hour. A single lamp would thus burn six hours without requiring any attention, at an expense of not more than seven cents for material consumed, to which, of course, must be added the cost of generating the current. A Gramme machine, driven by an eight-horse engine at the rate of 1,500 revolutions per minute, sustained 12 Jamin lights, each equal to 32 candles." It was found that with a machine making 1,200 revolutions per minute, and a wire one-twenty-sixth of an inch in diameter, the lights could be sustained on a circuit of five-eighths of a mile; by doubling the size of the wire and increasing the revolutions to 2,000 per minute, a circuit of 10 miles could be maintained with the same light. The Gramme is a French company with a capital of 8,000,000 francs, and the name of Gramme, the inventor is a man who is proprietor of about 60 gas works.

The employees exceeds than for has been won by the Brush machine during the 18 months for the Consolidated Electricite, in contract with the Metropolitan Board of Works, have maintained the lights on the Thames embankment without missing a night's light. The lighting was recently suspended for a few days for the purpose of cleaning the engine, which has been running. The Jablochkoff light has been successfully used for long distances and on a large scale, the Avenue Opéra having been lighted for 1½ mile with 400 lights for two

105

months. The Anglo-American Company has been formed, with a capital of £1,000,000, to purchase and apply this system. On sixteen engines is being erected in the South Kensington museum for use in connection with the Brush light. A large court, now lighted by 1,700 gas jets, is now lighted by eight Brush lamps, at a cost of 1s. 8d. per hour, a saving of 10s. per hour as compared with gas at the London price of 60 cents per 1,000 feet. Here, as well as at the British museum, the great advantage of the electric light over gas consists in the fact that it is entirely odorless and void of danger, while the combustion of gas is destructive to paintings, decorative work and bookbindings. In a large biscuit factory at Bermondsey the light is found to possess the peculiar advantage of enabling the workmen to distinguish the most delicate shades of color, a matter of necessity in their business. Shoreditch is also to have a Brush light, and the contract is about to be let for the lighting of Leeds, intending to supply the light from a central point over a circuit of 10 miles with. The Siemens light has been permanently adopted by the British Museum, and is in use on a large scale at the Victoria docks. The improvements recently made in the Gramme machine have increased the power of the Werdermann light, and its capability of subdivision—in which respect it is said to surpass all other lights—has led to its application to domestic use on a considerable scale in Paris. The supply of electricity is generated at a central point, and the light is had on by wires wherever required with as much ease as gas. A Werdermann light equal to 300 candles, requires the use of only one-half horse power, and a four-horse engine will maintain 20 lights each, equal to 300 candles. A notable feature in the progress made by all these lights is in reduction of operating expenses.

In conclusion, we may add that for European gas companies the electric light is having much of its terror, not because of a conviction that its competition must be feared, but because gas manufacturers are becoming confident that there is ample room both for the electric light and for gas. M. Jamin has made efforts to ascertain the views of representatives of the gas interest at Paris of the absence of any fear of the electric light, and from the following language of one of its number, M. Jordan, it appears that they are inclined to take that view.—*Iron.*

Metropolitan Gas Meter Inspectorate.

Appointments to the Metropolitan Gas Meter Inspectorate are announced by the Salt Lake Tribune of the 12th inst. that the Walker Bros. of that city have contracted to construct the largest of the Brush electric light for one of the largest sand machines with 14 lights, with which they will illuminate their quartz mills at Walker-ville, Montana. The mills will be employed about the works as follows: seven will be used in the large mill, four in the small ore, one in the hoisting works, and two will be placed at the lights in the dumps. The motive power afforded by this number of lights will enable the men to work at night as well as in the daytime, while the expense will be less than that of the present lights. It will be the first instance of the employment of the electric light in America.

Electric Power for Domestic Lights.

A Frenchman, Gaulard, has devised a plan for reducing the glare of electric lights, which he claims to be much more economical than ground glass globes. He makes his lantern of glass tubes filled with finely spun glass threads or glass wool. By reflection from the glass threads the light is given the desired diffusion, with a loss of illuminating power not exceeding 10 per cent, against 30 or 40 per cent with opal or ground glass. The natural blueness of the electric light can be corrected by tinting the glass tubes or the inclosed wool.

Electric Lighting.

Mr. Thomas Parkinson, has devised a simple for obtaining a constant current of electricity, under the varying degrees of electric lights, which he claims to be much more economical than ground glass globes. He makes his lantern of glass tubes filled with finely spun glass threads or glass wool. By reflection from the glass threads the light is given the desired diffusion, with a loss of illuminating power not exceeding 10 per cent, against 30 or 40 per cent with opal or ground glass. The natural blueness of the electric light can be corrected by tinting the glass tubes or the inclosed wool

parties. Indeed the device acts as the regulator does on a steam engine. If the carbon feeds too fast it checks it; if too slow it hastens it. It is in constant[illegible] to have the machinery and light on at the[illegible]ition at the depot to-morrow evening from 7 to 8 o'clock, and possibly later, if practical assistance that may[illegible]ed to secure steam power to operate the generators. The Ralgate Theatre extension is to arrive here at 7, and remain until 7:45, and will be accompanied by a[illegible]ht car, which will be run over the depot the light that hour is very slight, within the depot the light will produce a strong glimmer on the rails, and will show[illegible]ower, or even to contend with daylight, and serve a very[illegible]ortunity to the reception of the excursionists.

Several of the Sacramento[illegible]ave already been ordered for use in hydraulic mines, and it would seem, therefore, from this very practical statement that Sacramento is indeed to enjoy the credit of the solution of the electric light problem.—*Sacramento (Cal.) Record-Union.*

Oct. 4, 1879.

THE METROPOLITAN.

Electric Lighting at the New Docks.—A most important and interesting trial of the electric light as a means of illuminating the open spaces and quarters of warehouses took place on Monday evening last at the Royal Albert Dock at Silvertown, which, it will be remembered, was formally opened by their Royal Highnesses the Duke and Duchess of Connaught in June last. Some short time since, we alluded at considerable length to the preparations that were then in progress for the employment of this mode of lighting at the new dock, and in view of the extensive scale on which it was evident from the first that the trial would be made, the first lighting up by this means was anticipated with very great interest. As a natural consequence, there was at Silvertown on Monday evening a large gathering of scientific and other gentlemen interested in the subject. The subjoined account of what was seen and learned by those who had an opportunity of being present on the occasion has been furnished to us, and we would direct the particular attention of our readers to what is therein stated. It is for such purposes as this of all others that the electric light is likely to be found most suitable, and we observe, with considerable pleasure, the success of the experiment.

It will be remembered that the Royal Albert Dock is an extension, and a gigantic one, too, of the Royal Victoria Dock at Canning Town, consists of an entrance lock at Galleons Reach, approached from the Thames by a new impounding basin. The entrance lock is 1,000 in length, and opens into a tidal basin, having a water area of 32 acres. The tidal basin is 1,400 long by 1,000 in width, and has a water area of 72 acres. Attached to the east side of the tidal basin, and on its southern side are two impounding docks, one 2,600, and the other 500, in length. The whole of the entrance area, which is about a mile and three-quarters in length, is now electrically lighted by **46 lamps on the Siemens system. To the Siemens are fixed** four generating stalkes of machinery-houses, two of which are placed on the north and south sides of the north basin, near its junction with the entrance basin, and two more in similar positions at the western end of the impounding basin. In each of these engine houses are placed two nominal horizontal steam engine, which, together with a boiler of the same power, are supplied by Messrs. Marshall, Sons, and Co., of Gainsborough. The generating apparatus at each station consists of seven Siemens machines, each of which is of 16 lights, each of which is of 2,000 candles power, so that the total light, and from which a very powerful light is emitted. Of these lights, two are placed at the pier-heads, two on either side of the entrance lock, three around the tidal basin, while in rows on either side and on the south side of the main basin and entrance are placed the remaining 36 lights. Additional lights will eventually be placed above a clock tower at the western end of the basin, which tower has yet to be erected. The lamps are so distributed as to secure the best illumination at the dock gates and entrance bridges, and to afford sufficient light for the guidance and carrying on of the traffic along the quays and on the dock pathways. The lamps are hung from the stations to the lights are partly carried on lattice-work poles and partly conveyed underground in the form of cables. As the distances between the lamps and the generators vary from 1,100 to 1,400 yards, and the thickness of the leads has been selected with a view to compensate as much as possible for this difference and thus to equalize the intensity of the light. The Siemens regulators are enclosed in lanterns, which have been expressly designed to protect them against the weather, and they carry carbons of sufficient length to allow for 10 hours' consumption. Arrangements are made to admit further extension of the light space, power being reserved for supplying a small number of lights from each station, or up to[illegible] all. Such, in general terms, are the arrangements of this most recent example of electric lighting, which, simply regarded as a mechanical[illegible], is, perhaps, the largest yet attempted. The visitors included the chairman of the Dock Company, Sir George Chetwynd, the director, Colonel Strahlenie, the general manager, and many others. They proceeded to the new Royal Victoria Eastern Railway from Liverpool-street, and on arriving in the Royal Albert Dock, soon after 9 o'clock, were conducted to one of the sheds on the north side of the dock, which was lighted by electricity in order to show what could be done in the way of internal electrical illumination. This shed, which is 300 ft. long by 120 ft. wide, was lighted by means of eight small lamps, worked by a single electro-current machine, which, with its exciter, was placed in No. 3 electric-light station, close by. The shed was simply lighted—perhaps a little too fully—and during the evening the lights were very steady. Alongside the quay outside this shed lay the *Calvados*, a vessel belonging to the Orient line of steamers, and which had arrived that evening, and was the first vessel docked by the aid of the electric light, her docking having been most successfully performed. In the shed were some of the passengers and their luggage, which was being removed. Besides the eight small lights in the shed, there were two lights in the electric-light station No. 3, worked from the same pair of machines. This station was the visitors next repaired to, and after having examined the engines and machinery they proceeded to the roof on the extreme north-western corner, where they had the benefit of seeing the excellent effect of the electric-light in commanding the whole view of the entrance. Returning down the tidal basin, they were conveyed in a steamer which was in attendance to convey them to the small wharf in the graving docks, the object being to observe the effect of the whole series of lights from the basin. Unfortunately this object was defeated, inasmuch as the whole of the lights were extinguished just as the steamer was leaving her moorings. The reason assigned for this unlooked-for extinction was that the water supply to the boilers had run short, it being then half-past ten o'clock, and the engines exhausting been started at 6 o'clock. However, sufficient had been witnessed to demonstrate the practical value and efficiency of the system of electric light for the docks. During the time the visitors were at work on the docks, while it continued the lights exhibited great penetrative power, although, of course, they fell much of their useful effect. Considerable, too, the newness of the system, was the economy, the lights burned very well and were steady throughout. Upon the steamer arriving at the landing place one of the electric lights close by was started, and how its effect will be to the visitors while disembarking and returning their train which landed them at Fenchurch-street station at midnight. L.

The Telephone in Coal Mines, 1850

Could have been anticipated the following upon this subject:—"There are difficulties connected with the application of electric lighting to coal mines, which, however, are not insurmountable. The first one to the use of the telephone as a means of communication between the miners and the upper world. In order to communicate with the outside ground. The advantages of the telephone would be manifold in the ordinary routine of the pit. In the only colliery in which, we believe, it is in use, the engineer above is able to satisfy himself as to the condition of the pumping machinery in the parts of the works the most difficult of access, by merely listening to the sounds given out by the valves, &c., independently of the advantage of sending immediate advice or instructions on an emergency; and it is evident that, in case of an explosion, were the wires properly protected, the communication they would afford with workmen suddenly entombed alive would be of the utmost importance. On this last account the establishment of means of instantaneous communication with those employed in mines has, we are informed, been already enforced by one of the Australian Legislatures." //

ELECTRICAL ILLUMINATION OF MONTE CARLO.—The *Elektrotechnische Zeitschrift* reports that the first experiments with the electric light on the Venetian railway took place recently under the direction of M. C. Molecchott and of the engineer Girolamo Taddei, who represents in Italy the firm of Siemens and Halske. Only fourteen differentiation lamps were used, being maintained in action by a dynamo machine of medium size giving alternating currents. //

One of the difficulties experienced in bringing the electric light into use is the production of a uniform shadow across from a slight perturbation of the travelling power. The equal and ground-glass globes, with which we have hitherto been concerned, remedy this to a great extent, but the light is then[illegible] by the electric arc—a serious loss in many difficult cases. In order to obtain the mean,

The city council of Akron, O., has unanimously adopted the report of its[illegible] committee in favor of electric light and has empowered[illegible] to proceed with[illegible] Two letters to it, by 40 inches.....

Cost of engine and boiler foundations	$1,500
Cost of engine and boiler[illegible]	2,000
Cost of 2 engines at[illegible]	1,600
Cost of 2 boilers at[illegible]	1,000
Cost for[illegible]	250
Electrical machines[illegible]	1,000
Total	$7,700

THE *Electrician* Oct. 1 1879

RESPONDS: ELECTRICAL ILLUMINATION OF THE OPERA HOUSE AT PARIS.—Writing on this subject, M. Hospitalier says:—We may assert that the electrical illumination of the Opera will be *eclectic*, whenever it may be carried into effect: it is easy to show that this must be the case. The *foyers*, the *loggie*, the entrance halls, &c., may, without inconvenience, be lit up by the Jablochkoff *bougie*, or any other; but this kind of light must be rigorously banished from the house and from the stage, for the Jablochkoff *bougie* and all the apparatus in which alternating currents are employed produce a certain sound which is more or less intense, but which is always undissimable in a place where a *religious* silence is occasionally in the highest degree requisite. A journalist has happily characterised this peculiar matting sound by comparing it to a *ballet of cockchafers*.

Electrician Oct. 1 1879

// THE ELECTRIC LIGHT AND LANTERNS.—A recent number of *Le Gaz* thus sums up the principal defects of the most renowned systems of electric lighting:—"Jablochkoff Candle: Too much scintillation; no arrangement for relighting autonomically in case of extinction; too deep shadows beneath the lamp. Werdermann Lamp: Absorption of a great portion of the lighting power by the upper carbons; too frequent changing of the incandescent carbon; too much shadow. Jamin Candle: Too much noise; light too unsteady. Regnitzen—Serrin, London, Brush, &c.: Too costly: too much shadow beneath; delicate manipulation." Therefore, remarks our French contemporary, "there is still no really practicable system of electric lighting extant except the Serrin or Brush regulators for lighthouses or large works." Beyond this important negative result, the experience of four years working of the electric light in Paris, although aided by large subsidies, much financial support, and a certain amount of public favour, has produced absolutely nothing. We are inclined to think our contemporary is a little behind the times, and that a little keen appreciation of the progress recently made by Brockie, Crompton, Siemens, &c., in England, would enable one to place a different construction upon the existing phase of electric lighting. //

THE ELECTRIC LIGHT AND LANTERNS.

A recent number of *Le Gaz* thus sums up the principal defects of the most renowned systems of electric lighting:—"Jablochkoff Candle: Too much scintillation; no arrangement for relighting automatically in case of extinction; too deep shadows beneath the lamp. Werdermann Lamp: Absorption of a great portion of the lighting power by the upper carbons; too frequent changing of the incandescent carbon; too much shadow. Jamin Candle: Too much noise; light too unsteady. Regnitzen—Serrin, London, Brush, &c.: Too costly: too much shadow beneath; delicate manipulation." Therefore, remarks our French contemporary, "there is still no really practicable system of electric lighting extant except the Serrin or Brush regulators for lighthouses or large works." Beyond this important negative result, the experience of four years working of the electric light in Paris, although aided by large subsidies, much financial support, and a certain amount of public favour, has produced absolutely nothing. We are inclined to think our contemporary is a little behind the times, and that a little keen appreciation of the progress recently made by Brockie, Crompton, Siemens, &c., in England, would enable one to place a different construction upon the existing phase of electric lighting. L.

ELECTRIC LIGHTING.—The *Staten Herald* gives the following account of an American experiment made on September 2nd:—" A number of[illegible] of powerful electric lights was made last evening in the vicinity of the Sea Pavement, Long Branch, and the[illegible] was witnessed by quite a[illegible] interested spectators. The Northern Electric Light Company have[illegible] a powerful engine and dynamo-electric machine of the type, and mounted upon each of these elevations a tower of 12 electric lights of the Weston patent, each light being estimated at 2,000-candle power. As the towers are but 100 feet apart and in a triangle, it will be seen that the light of 30,000 candles was concentrated within a limited territory. The design of the exhibition was to afford a model of the plan contemplated for lighting the entire beach overhead in vast areas, the estimate being that four towers to a square mile of area, each mounting lights aggregating 90,000-candle power, will suffice to flood the territory about with a light almost equal to midday. Last evening a motive power of 25 horses was used in generating the electricity from three Weston machines, and the lights, with one single slight flicker, burned steadily and brilliantly all the evening. The[illegible] of the towers was also greatly improved by the[illegible] of reflectors, which were sufficient to allow two base-ball nines to play at the centre of the field lighted a game of the[illegible], with a score of 45 to 16, but, on account of the uncertain light (resembling that of the moon at sea), the batting was weak and the catchers were poorly supported. A trip on the Nantasket Beach Road to Point Allerton, about a mile from the lights, showed that the rays were discernible even at that distance, though the intervening territory was but little affected beyond an eighth of a mile circuit. The lights appeared to illuminate a larger area on the water-side than on the land, the Sea View House and its surrounding[illegible] being but[illegible] affected, while[illegible] beyond the[illegible] of the[illegible]. The claim put forward by the company is for a saving in the matter of lighting rates and taxes by grouping and concentrating electric lights of any kind."[illegible]

ARTICLES.

INDUSTRIAL USES OF THE ELECTRIC LIGHT.

IN an interesting pamphlet just issued Mr. R. E. Crompton, whose successful utilisation of the electric light is well known, reviews the question in its present aspect with a fair degree of impartiality, considering that to some extent he is naturally biased in favour of the "new" method of illuminating. Although experimentalists have not yet done with the light, for they recognise the possibility of further discoveries, it has left their hands in a practically perfect shape, and it is for the mechanical engineer to utilise the principles now well understood. Referring to the books on the electric light, issued within recent years, Mr. Crompton justly says that though bulky they contain little information of practical use, and are mainly histories of early invention with a sufficiency of newspaper cuttings describing recent ones, most of which have failed to stand the test of actual use. The accounts of working cost, too, are in many cases misleading, as the reports of engineers more or less interested in the success of the apparatus to which they refer, and too frequently they are treated confidentially with authors and with known facts. Mr. Crompton also condemns as dangerous generalisations the use of a number of useful facts which may be found of value by those who are engaged in introducing the electric light into new districts, and he indebtedness to Dr. Monsel, Dargaye, Latimer Clark, Hearder, Hopkinson, Muirhead, Preece, and Stocks-magines, in describing the various carbons, &c., he likewise mentions, rather superficially, that he regards lamps in modestly confesses that he has been engaged in perfecting the very device during the past two years, he judges himself to be peculiarly unfitted to the exclusion of others. He divides the systems of electric lighting into two classes:—

1. The incandescent, the most notable of which are those of Swan, Edison, Sawyer-Man, Edison, and Werdermann; 2. those using alternating currents, either with regulators or candles, as the Holmes, the Siemens, the Jablochkoff, Siemens, Wilde, and Lontin; and 3, those using continuous current machines with are regulators, which the principal are those of the Gramme, Siemens, Brush, Burgin, Crompton, and Weston, and the most used forms those of Serrin, Siemens-Siemens, Brush-Burgin-Crompton, and Weston. He adds the following definitive purposes of the Dubosq and Pournier patterns. Having thus classified the various systems into groups, Mr. Crompton discusses the first two as unsuitable for practical work, mainly for the following reasons:—The incandescent system, he says, promises well, but it must be always wasteful of energy, and consequently of horse-power, until some substance is discovered which is sufficiently refractory and stable at the intense temperature at which the incandescent system would be theoretically equal in economy to the are. Some of the modified incandescent systems, such as those of Hegnier, Andrez, and Werdermann have, he admits, attained a high degree of commercial success, especially for work on board ship; but he points out that the applications have been few, and in view of the uncertainty of the incandescent as to the best form of their apparatus, he considers that the whole subject has not yet passed out of the experimental stage. It must be confessed that the definition is just; but probably the main reason for the apparent neglect of the incandescent system is the fact that most of the inventors are endeavouring to perfect arrangements which will adapt the electric light for use in houses and public buildings, where a number of lamps of comparatively low illuminating power are required, rather than one or two brilliant, not to say overpowering, centres of light. That is confessedly Edison's main object, and other inventors are travelling on the same lines. Even supposing machines giving alternating currents, Mr. Crompton doubts the possibility of their competing on even terms with machines giving continuous currents, and he advises for the latter 35 per cent. more useful effect at the arc than can be obtained with the former. He also points out that as the object is nine times out of ten to illuminate a certain floor-area, and not waste light on the walls and ceiling, the space lost by the positive carbon is a natural advantage in favour of the continuous current system. The alternating current, on the contrary, has the two carbons equally consumed. As a consequence, the light is thrown in all directions above and below the horizontal plane passing through the arc, necessitating a large proportion of it being lost downwards as a long way is forcible to a dozen men. Four instances in an hour, with the light blazing full up or movement of the carbons, announced by a flicker of an inch, has a vastly greater effect than if the are were 1-8th of an inch, and with very rapid are the flicker is a tendency of the negative carbon to take a sort of mushroom shape from accretions received from the positive pencil. These are of course accessible to such an extent as to build up the are sufficiently to break and spoil their invariably-coarse hissing and unpleasant fluctuations. Crompton has been a standard as internal resistance of one ohm for his machines maintaining the arc of 5lm., with a pure white light. Brush, on the contrary, uses external resistance, some of his machines maintaining a resistance of one ohm for the arc of 10lm. Crompton, these high-tension are are unsteady, and the fluctuations. Crompton therefore thinks that if Brush had cemented himself with four lamps, four low-tension arcs would have obtained good results. He alludes to the lights at South Kensington and Liverpool-street station as bearing out his argument. Crompton's machines for the latter will be inclined, we imagine, to agree that the system there adopted is really very successful. Referring to the rather absurd statements which have been made with regard to the are, he agrees with Mr. Preece that instead of comparing the electric light with the candle-power used for gas, it should be with the illuminating power which a certain floor-area to a certain standard, and he gives a useful table for which several of the best known machines are thus compared. Omitting the machines from a merchant's point of view, he includes only those which are to the Siemens, and the Burgin, which, he says, "generally will give a little better than either. As to regulators, Mr. Crompton naturally considers them the best, and if we may judge from the ever-lessening number received, it is the best in the market. The inventor's great point is delicacy of adjustment, and he establishes that all the good machines rival one another so closely in economy of working that it is for secondary importance for the intending user to look at other points. The interior mechanism of the machine itself; the firmness and durability of the construction are particularly considered, and the probable wear and tear and risks of damage in working. As to resistance, the machines of Siemens and Burgin give, as a rule, the lowest tension currents, *i.e.*, have the lowest internal resistance; only one are can be burned in circuit, but the light is beautifully soft and steady. They have low windings and consequently small waste of heating from 1 to 2 are in the circuit, and the Brush machine gives a current of sufficient tension to burn 10 are in series. In comparing the Siemens, Crompton says that as we increase the tension and diminish the quantity of current we gain the power of burning more than one light in series, but the outlay is out and about $100,000), but it gives by the glowing of the carbons a much whiter light, which is often unpleasantly coloured purple, blue, or greenish; moreover the use of the arc is no longer confined to that point where the two carbons touch, but the whole current need nearly, but large enough, thus the light is of unequal brilliancy when viewed from different directions, and unsteadiness are clearly perceptible. If then the object is to light large spaces where the lamps can be placed at a considerable height, and where good colour and steadiness are desirable, Mr. Crompton advises the use of low-tension currents and single lights; but he does not think that for some scale are will ever supersede Siemens has done throughout, and Gramme in his larger machines. For purely mechanical reasons currents of very low tension are objectionable, and there is a long way in favour of a dozen are

The Electric Light for Industrial Purposes. By H. E. Crompton [Manchester: Palmer & Co.]

Mr. Crompton has collected in a pamphlet of some forty odd pages a large amount of information which he, in his capacity of engineer and contractor, has felt to be wanted. He commences by referring to the systems of electric lighting in use, grouping them in classes, and pointing out that practically the incandescent past the experimental stage, or to have been commercially successful when tried. The greatest advance has been made with the system employing direct currents; of such machines we are told there are upwards of 2,000 in Europe and America. With regard to the motive power there is little or no difficulty. Mr. Crompton says first-class engines can be had from fifty different builders, and speaks in high terms of the engines supplied by Marshalls of Gainsborough, and Ransome of Ipswich. A good deal of information is given about accumulators, and the experiments made with them are carefully criticised. The author lamps per horse power, viz., the ground area lighted to a certain standard. The labels given observe careful consideration. In speaking of lamps, Mr. Crompton admits a bias towards his own lamp, which discussion on carbons. These produced by the electric light know how important it is to have good carbons and how difficult it is to obtain them. Mr. Crompton states the defects carbons are and he gives a list of prices which will enable the reader to obtain a fair idea of the cost of such lights for a variety of purposes.

The Electric Light for the Merv Expedition.—We understand that the Jablochkoff Electric Company in Russia have just completed, under the personal supervision of Professor Jablochkoff himself, the machines specially designed for use at Kamyschlar, where Colonel Alikhanoff and Skobeleff intends making use of the electric light during the impending debarcation of Caucasus troops from the Volga for the Turkomans campaign. The three machines, with 2,200 candles, leave St. Petersburg this week for the Caspian.—*Globe.*

Scotsman Journal Oct 16 1880

Sir William Thomson's Lecture.—Lecture on Saturday afternoon. Professor Geikie, having sketched briefly, the geology of Edinburgh, first and the Salisbury crags, and called special attention to the existence of the Edinburgh coal-field. The geological features of Princes's Street, the new premises of Mr. D. Nicolson, where they were entertained to tea and other refreshments. Mr. Nicolson's factory, which has few, if indeed any, equals in the country, was visited and greatly admired. Mr. Nicolson's residence and its grounds. Mr. Nicolson has apart, connected by means of the telephone, and arrangements had been made for the lecturer and friends to observe the working of the exhibition. [illegible] privilege that was eagerly taken advantage of.

Dr. Bikmore, on Health, said:—"It is not, perhaps, alphabetical in the case of the electric light, but the question of the effect the light may make a considerable change in the conditions of some kinds of labour. The influence of light on vital powers is one of these. It does not always favourable, and that is in this country still reading by men from the sun, and not aware of any the Arctic Circle; but we can have prolonged daylight of bearing on animal life from Siemens' interesting experiments on the effect of the electric light on the vegetation [illegible] as Darwin pointed out, the 'sensitiveness' of the eye is also their highest vigour or perfection of vision, side, or under similar conditions."—*Scotsman*, August 11th, 1880.

INCANDESCENT ELECTRIC LIGHTS.

On Wednesday evening in last week, Mr. Joseph W. Swan delivered before the Literary and Philosophical Society of Newcastle-on-Tyne a lecture upon "Electric Lighting," which would not deserve notice in these columns were it only on account of the original matter contained therein, but as much of the subject adopted by the author, but Mr. Swan's lecture has more especial claims upon public attention from the fact that in it the author describes a series of highly interesting experiments which he has been constituting through periods extending over twenty years, and which have led him to the discovery of a system of illumination which appears to solve not only the long-vexed question of the subdivision and distribution of the electric light, but one by which a number of small lights suitable for private houses can be actuated from a central station, and at a cost which compares favourably with that of gas illumination.

After a few preliminary remarks in reference to the general principles upon which the application of electricity to illumination depends, and while referring to the various modes and appliances for generating electric currents, the author takes advantage of the reference to voltaic batteries—which are now of so high absolute resources of illuminating currents—to point out that the voltaic cell is that modified form which is known as the secondary battery, and which was first introduced some twenty years ago by M. Planté, is likely to play a very important part in the development of electric lighting, not as a generator of electricity, but as a sort of reservoir for what may be called "storing up" electricity which has in the first instance been generated and rendered by a dynamo-electric machine. Without describing the secondary battery of M. Planté, the author here says our readers that it consists generally of two sheets of lead placed very close to one another, and immersed in a cell of diluted sulphuric acid. When these plates are respectively connected to the opposite poles of a voltaic battery or other generator, the oxidation of the surface of the one, and that the deoxidisation of the other so far alter their relative electric condition that for several hours after they have been disconnected from the exciting battery they are capable of giving out an electric current, and reassembling it through a circuit connecting their poles, and by forming a number of such secondary cells together, powerful currents of high electromotive force may be produced and rendered available for considerable time after they have been charged by the primary battery. In reference to the beauty of the author Mr. Swan pointed out that in the secondary battery a solution such as sound is the only products of working up a source of electricity by which electric lights may be sustained for considerable periods of time, and that without the stopping of the dynamo engine. The author then described the system of electric lighting of a successful means of keeping a number of lights of the same intensity independent of the variations of the prime generator and of the speed at which it was driven, and was shown how each lamp could be all automated in the think that the author had made a great step in the development of electric illumination when Mr. Swan few having so prominently drawn attention to the means by which it may be brought about.

After a passing reference to thermo-electric generators, which have been applied with a certain small amount of success to the production of the electric light, the author proceeded to consider the most salient features of the two great divisions of the subject of electric illumination, viz., lighting by the electric arc and lighting by incandescence, preferring his remarks with the following division of the two systems: "In lighting by the electric arc there is a break or gap in the circuit which has to be bridged over by a sort of electric flame. In lighting by incandescence there is no break or gap at this point where light is produced, but a thin, highly infusible, and highly resistant solid substance is there interposed which becomes white hot, and emits a light, bright in proportion to the degree of heat produced in it." As our readers are already

Nature Oct 21 1880

THE JABLOCHKOFF ELECTRIC LIGHT.

Not very long ago it seems was instantaneously killed in Manchester by inadvertently touching an exposed conductor of an electrical lighting apparatus; and the public doubts as to the safety of the new mode of lighting which the event caused will probably be reawakened by the news of the recent fatal accident on board the Inman steamer *Oregon* during her trial trip from the Clyde to Brest. It appears that on Saturday, the 16th inst., one of the stokers of the ship was asked to hold an electric lamp, by which was being carried out to light the stokehole. The man, being ignorant of the danger, grasped the lamp by the brass rod which runs round it, and at the same time inadvertently touched one of the bare wires which supply the electric current. By this act he interposed his body in the track of the powerful current which was in part at least diverted from shock to arrive like a flash, and struck with sufficient force to throw him down dead, all efforts to resuscitate him being unavailing. There was the effect due to heart disease induced by the blow as is sometimes the case with concussion of the muscles, for no wound was found upon the body that the tissues of his body had been disrupted to such a degree by the discharge that immediate burial was resorted to.

THE ELECTRIC LIGHT IN ANTWERP.

Jamin's Electric Light.—We understand that instructions have been given to proceed with the lighting up of the Royal Panorama, Leicester-square, and adjuncts with thirty Jamin's electric lights. The directors and artists of the Panorama have carried out some extensive trials at the works in Paris, and were so satisfied that they have decided upon adopting this system. *Electrician Oct 16 1880*

The Electric Light in Paris.—M. Charles Garnier loudly demands the introduction of electricity, so as to preserve from destruction the works of art with which he has decorated the Paris Grand Opera. To descend from the sublime to the comic—from the Grand Opera to the Palais Royal—this latter theatre has been entirely redecorated, and in so remarkable a manner that it merits a few words of notice. M. Bayard has been entrusted with the work, and has painted on the walls of the *foyer*, or crush room, a biographical history of the theatre. On one side we have grouped representing all the ancient actors in their most celebrated parts—the Père Amant, Bontin, Rigaud, and Mlles. Perron, Nathalie, and Mars. To unite the past with the present there is an allegorical group of nymphs and satyrs, and then we find the portraits of all the celebrities who still entertain the gay audiences—Bressaut, Hyacinthe, Ravel, Scheneider, &c. But we are reminded that these new and elaborate decorations, which possess the double attraction of works of art and works of history, will be prematurely obliterated if they are exposed night after night to the blaze of innumerable gasburners. The Gymnase Theatre has also been redecorated, [illegible] *Oct 9 1880*

THE GAS AND ELECTRIC LIGHT EXHIBITION AT GLASGOW. *Oct 16 1880*

TO THE EDITOR OF THE ELECTRICIAN.

Sir,—Your correspondent describing the above is hard on us exhibitors of electric light apparatus, saying that we are always behindhand, and, when we do show, do not show at our best for some time. I think if you consider that we have to supply the entire plant for the production of the electric light, viz., engine, dynamo-electric machines, cables, connections, lamps and lanterns, wherever one exhibitor has the very exclusive use gas supplied to them from the mains laid on ready to their hands, and have only to hang up and attach a few lanterns and burners to make a very effective display you will see how to go far for the explanation. The exhibitor of gas apparatus had burners shown on the opening day, I do not think the gas of the exhibition would be quite so brilliant as at present, and I think it is just possible that they might be a few kitchen and sanitations of the light even among the gas exhibitors during the early days of the exhibition.

Speaking for myself, all my apparatus has been ready for showing the light for some days, but I had an engine to drive and dynamo-electric machines. This has arisen from an unfortunate misunderstanding regarding the supply of the steam power, which has made my engine late in arriving. I have no doubt others are in the same position.

I beg to correct your correspondent in some few mistakes he has fallen into regarding the exhibition.

The British Electric Light Company are not exhibiting at all. Messrs. De Clark, Reichhead and Co. are exhibiting the Lontin light, the Anglo-American Company are to exhibit the Lontin light, Strode and Company show the M'Kenzie and Dyer system, of gymnotus in my own name. I have not heard who is to show Hrochki's lamp. In a few days I believe that there will be a fine display, and your correspondent will have nothing to complain of the year's exhibition has taken place at the very busiest season of wondered at that many gas firms could not afford to send skilled operatives to remain with their stands for a month.—Yours, &c.,

H. E. Crompton.

Mansion House Buildings, London, Oct. 9.

well acquainted with the essential characteristics of both systems, we will pass over that portion of his lecture in which the author treated of lighting by the electric arc, and pass at once to his remarks with respect to that branch of the subject with which his name must more especially be associated. In speaking of platinum (or an alloy of platinum with iridium), and carbon, He then went on to compare the merits of the two substances, showing that while platino-iridium possesses the advantage over carbon in being incombustible in air, it is incomparably inferior to carbon in infusibility, the latter substance having resisted without fusion the very highest temperature to which it has been subjected. In consequence, however, of its destructibility by combustion either in air or in imperfect vacua, carbon has been put aside by most workers in favour of its meltable rival, and our readers are familiar with the published experiments of Mr. Edison, and with the many modifications of his platinum lamp, in all of which provision had to be made for the protection of the platinum strip from destruction by fusion under the influence of an abnormally strong electric current. The author first pointed out the more especially those of them who a few months ago were possessors of gas shares) are also aware that Mr. Edison has more recently produced an incandescent lamp, in which a loop or horseshoe of carbonized paper was employed in the place of the platinum strip. This lamp, judging from accounts reaching us from the other side of the Atlantic, gave great promise of success; we have heard but little, however, of it since, and the obvious inference is that the experiment has not fulfilled the promises taken by its sponsors at its birth.

It is an interesting fact, however, as bearing upon the history of the subject, that as far back as twenty years ago, Mr. Swan designed and constructed a lamp identical in principle, and very similar in appearance, to that of Mr. Edison, and in which an arch or horseshoe of carbonized paper was employed. This early lamp of Mr. Swan is shown in Figs. 1 and 2, which represent the front and side elevations respectively of the apparatus. In it the carbon was in the form of an arch, about 1 in. high and $\frac{1}{4}$ in. wide, its ends being clamped in small square blocks of carbon; the whole was enclosed under a bell glass, which was fitted by an air-tight joint to a circular base-plate, and the air within the chamber so formed was exhausted by a common air-pump. When the lattery was connected, the paper and carbon became incandescent, and Mr Swan observed that its inner edge was raised to a higher state of incandescence than the outer edge, and in consequence of this the carbon horseshoe, seen edgeways, began to bend from its own centre, as shown at A, Fig. 3; on continuing the current the bending gradually increased, as shown at B, and at last the arch bent over as at C, until the top of the arch touched the base-plate, when it broke in half, and the lamp was destroyed.

The destruction of the incandescent carbon strips or rods has, until now, presented an insurmountable obstacle to the development of incandescent lamps founded on that principle, and the cause of this destruction has hitherto been attributed to a continual evaporation and deposition of the carbon under the influence of the enormous heat to which it is subjected, and this view was supported by the fact that after a short time the glass became dimmed and obscured by the formation of a kind of black smoke depositing a sprcie of soot over the internal parts of the lamp. More recent experiments of Mr. Swan have shown, however, that this phenomenon can be completely prevented by having a more

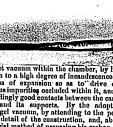

FIG. 1.

FIG. 2.

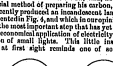

FIG. 3.

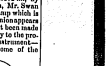

FIG. 4.

perfect vacuum within the chamber, by heating the carbon to a high degree of incandescence during the process of expansion so as to drive out all the gaseous impurities occluded within it, and by having exceedingly good contacts between the carbon horseshoe and its supports. By the adoption of the Sprengel vacuum, by attending to the perfection of every detail of the construction, and, above all, by a special method of preparing his carbon, Mr. Swan has recently produced an incandescent lamp which is represented in Fig. 4, and which in our opinion appears to be the most important step that has yet been made in the economical application of electricity to the production of small lights. This little instrument—which at first sight reminds one of some of the

small ornamental glass vases which are frequently used as ornaments of very great interest at the present moment, as it is much to be hoped that it may be improved, because, in the simple form described, it does not appear to us that would be required of a secondary battery, applied as a store of electricity on a large scale, for the purpose of lighting our streets and houses. In this case, we fear it cannot be said to have been either fully developed, but rescued in time at work seeking its complete fulfilment. There can no doubt that this task in course will be found, and with the perfecting of the secondary battery, that great objection to electric lighting—that you cannot store the power which produces it as you can store gas—will be completely done away with, and electricity will be applied to lighting purposes. The last question that we have to consider is the comparative cost of lighting by electricity—(1) that of lighting by the electric arc, and (2) lighting by incandescence.

The lamp used to illustrate the first system was that of Mr. Crompton, which was formed of a number of the electric lights of the former lamps were stated to have replaced at the Alexandra Palace from 2,000 to 3,000 gas burners, and in the case of the Inventions Exhibition, 1,000 gas burners. The system we should say, as

supporting it, the ends of the carbon were thickened; and, in some of the early experiments, electrotyping and burnishing of the ends of the carbons to platinum was resorted to. I will not describe these processes, with details, but simply say that the prescribed course, having been rigorously complied with, it was found, after some days' working, that the ends of the carbon were thickened, *the lamp glass was covered, and the conductor which supported it reflected, there was an incrustation of the globe, and an appreciable coating over of the carbon.* These was except many a particular error, but it was found that a certain degree of hardness or density must be in the carbon to produce a good thoroughness. It only remained to perfect the distribution of the current, so that it should flow from which the carbon was solidly clamped, but without the least resistance. These points, I think, I have now satisfactorily settled, and can confidently state that the lamp is practicable." The carbon in this lamp is a mere line, quite horizontal, and without any incrustation, and becomes harder by the heat of the burning longer and the better it is heated the better it becomes. It is exceedingly economical, for the reason that the resistance that the lamp offers to the current, and, *inversely*, the carbon used is not consumed in the thickness of the filament of the carbons formed by electrotyping, and, therefore, non-essential to the current, costing one-twentieth the price, will produce in this lamp a resistance to the same degree of brilliancy as twenty times current will produce in the ordinary carbon arc were used in these smaller lamps. The work of the Brush Company in the matter of the carbon lamp was then solidly discussed, but without result. The system of distribution was carefully considered, and appeared to be unexceptionable. The great corporate view was obtained, many capable also in the lighting of houses. In view of such application, two systems were considered, one on the distribution, and the other on the arc. Under the latter system the current was distributed, and measured as upon a dividend, distributive, and divided, and measured as upon a dividend. Under the former system, a fixed current was used, and very high authority that great loss necessarily attends the dividing of the electric light. To a certain extent this is true of lighting by the electric arc, but it is totally and absolutely erroneous of lighting by the electric incandescent. There is no loss in dividing the electric light conductor by the means. Parsday has stated that the law of the case in these words: "Any number of lamps in multiple arc will not lessen the work done by the dynamo, will not lessen the temperature 1000°, or an infinite length of the same wire, supposing no current to escape." Mr. Swan adds, "The economy of lighting by incandescence has not been exemplified by so many instances of a practical character, but it is, nevertheless, a fact, as certain as that electric lighting by arc is economical per se. The economy of incandescence is an economical proposition, demonstrated by the fact that 1000H.P. of an engine will actually light a gas engine to develop an electric current, and used to 20 horses, will yield results equal to 1000 lights of 20 candles each, the efficiency very in gas burners. This seem is now lighted by 1000 lights of 20 candles each, and by reason of the current which feeds these 20 candles, and by reason that the burner is a gas engine; before any loss of gas per hour are being was lighted by current per hour. Mr. Swan has stated on good authority, 200%, per hour. It is very evident that we have in certain quantity of gas used in gas engines, economical manner employed in any house, that would be obtained from this source. Mr. Swan has stated that the cost of lighting by incandescence that it is only one-third when, instead of the motive power of gas, that of steam is employed. Where gas engines, economical manner employed, this method of electric light, economical manner is not costly than gas lighting. I reckon that it will be very much less in saving of gas. I reckon that it will be very much less in saving of gas. I reckon that it will be very much less in saving of gas

ELECTRIC LIGHTING.*

Almost two years ago I had the honour of delivering a lecture in this place on Electric Light. To-night I have undertaken to report the progress which has been made in the interval with the subject. All the enquiries whether or not gas lighting was greatly prejudiced by the electric light. It was generally admitted that a revolution-working discovery had been made, and you may remember, as a consequence, that the shares of gas companies suffer a while, when the electrical engineer was introduced and joined in the delight of scientific examination, demonstrations and lectures. Then the gas companies set to work to improve their gas in place of the lamp and burner, which at first took possession of the public mind, there is now, I think, a reasonable confidence in the possibility of electric lighting, but the universally prevailing that electric light is a substitute for gas, is after all a theory.

The following remarks on the *present position* are here given, and the description of the *present practice of producing electricity by mechanical means* has been added.

On the production of electricity.

It is practicable to develop a horse-power by the combustion of 25lb. of coal per hour, and to produce with that amount of motive power a current of electricity sufficient to give a light of several thousand candles; that is, 1,000 to 2,000 candles, or 6 large gas-burners, or 12 of the more than equal to 1 cubic foot of gas per hour, and consuming 5 cubic feet per hour. Of the voltaic battery, or any other means of converting an electric current of present known, there is only one means of converting an electric current of electricity was discovered as essential to the voltaic cell, and the question of electricity. Mr. Planté was, I believe, the discoverer in the secondary battery of it. Many have since experimented, and I have myself, in the idea of a secondary or charged plated opposite each other and very near together, but not touching one another, and separated by the space of about one-eighth inch, or *viz., lead* and in the presence of *dilute sulphuric acid*. Now, the action of the same metal, voltaic battery, inasmuch as the combination differs from an ordinary battery in the absolutely of the two metals employed. The ordinary battery is zinc and copper, or zinc and platinum, or some such metal in part constitute it. It is that zinc is the one metal employed with an electrolyte of dilute acid. Now, in the secondary battery, the two plates are alike, therefore of the same voltaic battery. But if these two plates are first charged with the ordinary way with a generator of electricity, a current will flow as one set of the (presumably) oxidised, and the other reduced. This kind of thing may be used plates is changed on its surface—it becomes (presumably) oxidised, one of the other reduced as well as upon the other, and the battery is ready for use. condition or is to be able to give out, at any future time, a current of electricity on its own account. The process of charging is to send a current into the plates are, in a way, opposite, just in the same condition they were before receiving the charge, and are ready to receive another charge. The secondary battery, therefore, is a means of storing electricity. The battery is transient, and it is useful to be hoped that it may be of interest at the present time, when the question which I have described is being much discussed, to have it explained how the secondary battery, applied as a store of electricity, will work large scale for accumulating electricity for lighting. I have here a small, but decided, makes a very great noise, and I am glad to see that all that could be was charged this morning; I have not touched it since. I will now ask how will join the plates together by this platinum wire? It was nearly burnt. I will disconnect and the wire will become cool. Now, I will charge it again. The want of a means of storing electricity is now (by the use, white hot) cannot be a question of the practicability of the secondary battery. It has been completed in actual practice, and research is still busy at work. It has be completely fulfilled. Research is still busy at work; but it is not to be found, and with the perfection of the secondary battery that great object in electric lighting—that you cannot only produce the power when you—like electricity was here lately refused to.]

All the various methods of producing electricity that can make any pretension to practical use are divisible into two classes, namely—

1st. Voltaic electricity.

2nd. Electricity by magneto-electricity.

In lighting by the electric arc, it is the break or gap in the circuit which has to be bridged over by a spark of electricity before flame. In lighting by incandescence there is no break or gap at all, but a continuous circuit of high resistance, and it is the heating of this by the current that produces the light. In lighting by incandescence, therefore, a continuous solid substance is there between the terminals which, and such a light, which is prepared for use. Now, to do it most perfectly and I am talking about, I will first speak of the voltaic battery, and then—incandescence—is found in the secondary battery. A secondary battery, produced by a steam engine and dynamo-electric machine, is charged, and these two pencils of carbon are brought into contact, whereupon there is a stream of flame, the carbon is consumed; by increase of the space a much expensive one much expensive one and the current is consequently diminished, and when the distance of about a quarter of an inch is reached the light is found to be of the best possible character. The carbons are also made to approach one another by clockwork, and the current is consequently light is found to be of the best possible character. The carbons are also made to approach one another by clockwork, and the current is consequently arranged that each of the carbons shall receive a certain limit of consumption before the carbons are made to approach one another by clockwork, and the current is consequently also reason.

A certain *amount* of difficulty or resistance must be offered to the passage of the current in order to get the most light, and to get the best effect the resistance to be neither too much nor too little.

When the points are made to touch there is no longer the resistance of the air-space to be overcome in the circuit, the light consequently goes out.

Observe the alternations in the light, and how they depend on the distance between the points. Now, as the production of steady light depends on the points should be maintained at a constant distance, it is clear that under the complicated conditions of every-day use the question of the distance of the points to each other is a matter of extreme difficulty.

I will now ask for the carbons to be turned on to a large lamp of light, in order that you may see how very nearly the difficulties of producing a steady are fulfilled in the incandescent lamp.

The particular lamp I am using for the purpose of my illustration is that which is employed in the Holborn Viaduct Station. Properly-applied it fends the points together almost continuously and with great precision.

That, then, settles and *finally disposes of the question of Electric Light*. That is the form of electric light that inventors have for the last forty years struggled and battled with difficulty upon difficulty to render serviceable to the wants of man.

From the nature of the electric arc light you will easily perceive that it is a kind of light not suited to the lighting of dwelling house, nor shops, nor streets.

It does not lend itself kindly to division, nor extensive distribution. It will give you either a great deal of light or none.

The incandescent principle used is excellent. If you want a very brilliant light, and one concentrated in one focus, for a lighthouse or signal, for example, or for illuminating a large factory station, or very large workshop, or open space, it is unquestionably the most economical and the best of all artificial lights.

It has already found for itself in England over 20 appreciable applications. Its use is continued and increased on the Thames embankment. It is used in the main room of the British Museum; in the Union Library, Liverpool; in a portion of the South Kensington Museum; at the Liverpool Exchange; in the Grosvenor Gallery; in the Newcastle Water Co.'s Reading Room, Blackburn; on the Promenade at Blackpool; and at the New Albert Dock, Leeds. In all these cases the electric lamps are used in conjunction with gas, and are lighted by ignition by day, and at a very moderate cost.

As an illustration of the economical lighting by means of the electric arc under conditions suited to its use, I instance the case of an installation which cost £2,000 and is lighted with a consumption of 70 cwts. of gas per week, or 3,640 cwts. of gas per annum, giving the worth of gas per annum of £1,820. The £2,000 was borrowed, at a cost of 5 per cent., and some interest was given for the economy of the electric arc light is greater by half in the case I have mentioned, and it is probable an effect of general illumination can be produced by the electric arc light at a cost of 25 per cent. less than overland as well as upon the Continent.

The interest which attaches to electric arc lighting is much less than it was. It is not now a novelty, and it is not likely to be extended. Whereas, the incandescent light, as a rule, wants the light of 1,000 candles all in one place. Now, it is not generally want in a number of small places, dispersed in different rooms, and in different parts of another direction. For electric light of this description we must employ a subdivision of the electric current.

I said that there is another way of producing electric light; namely by magneto-electricity.

Lighting by incandescence is a branch of the subject which has a special and its I believe to be the best which will yield the largest crop of light. Electric lighting by incandescence is a subject which is not a very good conductor of electricity, highly infusible, and which, when heated to a high degree, undergo change in a vacuum. There are, so far as I know, no other substances which possess all the qualities I have specified in the purpose in question.

The two substances are Platinum, or an alloy of platinum with iridium, and carbon.

Platinum has the advantage over carbon that it is not consumed by the heat, but it has the disadvantage of you make it why you make it why you make it why

Nature. PHYSICAL NOTES [illegible] 1880

Mr. J. E. H. Gordon has lately patented a method of producing light from electricity based upon Mr. Spottiswoode's suggestion to apply the alternating-current magneto-electric machine of De Meritens to the induction-coil. Mr. Gordon arranges small balls of platinum or iridium, or of an alloy of these metals, at the ends of fine platinum rods in pairs in the middle of a suitable globe, and causes to pass between them a rapid succession of sparks whereby they are raised to incandescence. There is no consumption of carbon or any other substance, and the lamps may be connected either in series or in parallel branch arcs. The principal remaining disadvantage is the noise attendant on the rapid sparks. A mechanical contrivance is added to keep the knobs near together when no current is passing in the primary coil. The induction-coils used are of comparatively small size.

The Brush Electric Light Company has twenty-two lamps on Broadway, in this city, between fourteenth and thirty-fourth streets. The lamps are supported by iron posts twenty feet high. The station from which the electric force is supplied is in west thirty-fourth street. The generating machines already in use, and here in number and will each give current enough to supply sixteen lamps of the standard power of two thousand candles. Each fifty ordinary gas burners each. Each of these generating machines is about four feet long, eighteen inches wide and two feet high. The armatures make about eight hundred revolutions a minute. Fourteen machines, in addition to half a dozen more station light machines, are now ready for use. Forty-eight machines which is now nearly ready for placement from Glenfield. The company have introduced a cheap and effective fuel under their boilers; they burn the screenings of coal yards mixed with bituminous coal in the ratio of ten tons of dust and screenings to one ton of coal. The mixture costs about one dollar a ton and gives an excellent fire.

Electrician Nov 13 1880

The Electric Light.—The British Electric Light Company (Limited), through Mr. H. Bury, their agent, in Manchester, have introduced into the print room of Messrs M'Laren and Neylson's warehouse in George-street, a system hitherto practically unknown in that neighbourhood. Under Mr. Bury's superintendence there have been fitted up at Messrs. M'Laren's premises seven small divided lights, on what is known as the André system. Depending from the ceiling in lamp form, the lights are protected by glass globes, and fitted with reflectors, and their brilliant illuminating power is strikingly evidenced by the manner in which the various colours in the prints are shown up. Each light is said to be equal in power to six ordinary gas jets, and the system is held to be specially adapted for warehouses, printworks, steamers, billiard tables, dining and drawing rooms, and, indeed, any place where many small lights are required. The system has been introduced by the company in London and elsewhere, but this is the first occasion on which it has been shown in Manchester.

The Anglo-American Company.—We should have given any shareholder more credit for business acumen than the instigator of the subjoined letter, which was given in the money column of a daily contemporary :—"Sir: Referring to the recent correspondence with reference to the interim dividend announced by the Anglo-American Telegraph Company, we beg to inform you that we have received instructions, on behalf of a holder of deferred stock, to commence immediate proceedings with reference to the payment of any such dividend, and further to restrain the payment of any further dividends until the capital represented by two of the cables which are said to be lost be replaced.—We are, sir, your obedient servants, Tyrwhitt and Son, 9, King-street, Coventgarden, London, W.C., Nov. 1."

A new system of electric lighting by the incandescence of filaments of carbon was shown and explained at the Society of Telegraph Engineers, in London, on the 25th ultimo, by Mr. Swan, of Newcastle-on-Tyne. Mr. Swan claimed to have solved the problem of subdividing the electric light so as to render it available, when certain minor difficulties be overcome, for domestic purposes. Professor Tyndall, who was present, said that if the durability of the carbon could be proved by experiment, Mr. Swan's success was complete.

The Jablochkoff light is to be introduced by M. Heyre-Mangon into the Conservatoire at Paris. It will be fed by a Gramme machine which the Government has purchased for its constant use. The light will be placed in the amphitheatre, where M. Heyre-Mangon delivers twice a week his own lectures.

Engineering Nov 19 1880

The Brush Electric Light.

Last Friday evening the directors of the Anglo-American Electric Light Company received at their works in Vine Street, Lambeth, a number of scientific and other gentlemen interested in the subject of electrical lighting. The visitors included Colonel Festing, R.E., of the South Kensington Museum; Captain Linden, Naval Attaché of the Russian Embassy; Mr. William Spottiswoode, P.R.S.; several representatives of the Admiralty; as well as Sir Henry W. Tyler, M.P., and Mr. John S. Sellon (of Messrs. Johnson, Matthey and Co.), who are the chairman and vice-chairman of the company respectively; Mr. Nettlefold (of Messrs. Nettlefold and Sons); Mr. Montgomery, the acting managing director; and others. The object in view was to demonstrate that the company was in full working trim and were executing orders for every variety of application of the Brush system to illuminating purposes. The Victoria works are illustrated by various electric lamps, which are kept going by a 16-light Brush machine. A new machine, just completed, and about to be despatched to Portsmouth, was also started, and instantly an additional fleet of light, said to be of an intensity of 9,000-candle power, and which was very striking, and almost overwhelming, shone throughout the works, making it as light as day in almost every part of the building. It had at first been proposed to display this splendid light outside and at the top of the building, but this intention had to be abandoned on account of the high wind prevailing, which prohibited the exposure of the naked light, there being no glass-globe at hand.

The Brush system of electric lighting, which in a great measure owes its introduction into this country to the exertions of Mr. Sellon, is very extensively used in the United States, and is making rapid progress in England. The system was described by us on its first number for the present year, so that we need only now observe that the Brush dynamo machines—one of which we then illustrated—are made in several sizes, capable of operating from one to sixteen or even more lights in a single circuit, which may be ten or twelve miles long. In construction they differ in some extent from other machines of the same kind, both in the armature-field magnets and commutator; and they are so constructed that the moving parts, such as the segments of the commutator and Brush contacts, can be easily replaced when necessary, by an ordinary mechanic at trifling cost. The current obtained is continuous, but of a highly electromotive force, in order to overcome the resistance of a long circuit and a considerable number of arcs. The lamps are exceedingly simple and practical in construction. Its appearance they are mounted on open rectangular frame of iron, with a closed box above containing the regulator and the two carbons down the middle. They contain no clockwork, and no adjustment is required beyond replacing carbons when consumed. By means of an automatic cut-off each lamp may be wilfully or accidentally extinguished without sensibly increasing the brightness of the others in circuit, for the corresponding increase in their illumination is only one-sixteenth. The lamp is placed in position by simply hanging it up, so that it is in every way suitable for general purposes. The carbons are in the form of two cylindrical rods pointing to each other vertically. It is claimed for this system that by it the drawbacks of expense, uncertainty, and complicated mechanism, which have hitherto stood in the way of an extended application of the electric light, are overcome, and economy, constancy and simplicity secured.

The Brush system should be considered as rather the multiplication than the subdivision of the electric light—assuming that, instead of dividing a large light into a number of smaller units, with a loss in the total light for each subdivision, we rather multiply one sixteen-candle light, say 1000 to 2000 candle-power, into an increased number of lights of the same size, absolutely energy proportionately to the increase of number. By simple manipulation of the regulator, the number of lights may be diminished or increased, as required, to any degree up to the maximum number, with a corresponding saving of expenditure. One of the most important advantages of the Brush system, and which arises from its peculiar construction, is the great ease with which lights may be worked at a long distance from the machine with a very small loss of power. Again, one pair of conductors only is sufficient for all lamps, no matter what their number may be, and the loss due to these conductors falls, not on each lamp, but upon the whole circuit.

The saving thus effected is considerable and only of electrical energy, but in the first cost of wire leads.

Under the guidance of Mr. William Ladd, F.R.A.S., and Mr. Montgomery, the visitors were conducted over the works, which are very extensive. They were shown the various processes connected with the manufacture of the Brush machines and the electric lamps, the latter being of an exceptionally substantial nature. The display of the light at the works showed conclusively its perfect suitability for factories and workshops, the light being white and very steady. On leaving the works the visitors proceeded to the Liverpool Street Station of the Great Eastern Railway, where the Brush light is undergoing probation, and where its suitability for station purposes was evidenced. Altogether the demonstration was very satisfactory as showing the practical progress of the Brush system. The light will soon be seen at Westminster, where it is to be introduced on the Clock Tower of the Houses of Parliament. Moreover, in a short time it will be visible on an extended scale in the City of London, a considerable portion of which is to be illuminated by it, namely, Blackfriars Bridge, New Bridge Street, Ludgate Circus, Ludgate Hill, the north side of St. Paul's Churchyard, and part of Cheapside.

On Monday evening another opportunity was offered for inspecting the company's works and their system of electric lighting. The weather being more propitious, there was a display of the large Brush light (of 9,000 candle power) on the roof of the building. The visitors were taken by omnibus to the north side of the river and to Oxford-street, which was very striking indeed. The light seemed to annihilate distance, for in Northumberland Avenue it appeared to be but a few yards off, although faced at least half a mile away.

London Mining Journal. [illegible]

The Electric Light for Collieries.

Coal Trade Journal. Dec 4 1880

The arguments from time to time put forward in demonstration of the electric illumination was altogether inapplicable in collieries appeared to be in every way justified when considered with regard to the character of the electric light, the increase of safety and the production, and the consequent saving in cost, not to speak of its unreliability and the great trouble attending its use. But these views must have been very materially modified by the interesting paper by Mr. J. W. Swan, of Newcastle-on-Tyne, explaining his system of subdividing the electric light, read before the Society of Telegraph Engineers on Wednesday evening. The light produced by Mr. Swan's system is of the incandescence class, and the essential feature of novelty appears to be in the excessively small carbons used and the completeness of the vacuum in which they are burned. He maintained that even where the electric light as produced by the new was of greater subdivision, the maximum necessary to counteract its tendency to vary in power, the cost and trouble of replacing the carbons, and other disadvantages, would frequently diminish and frequently entirely neutralise the advantages of its economy and extreme brilliance. The moment the attempt was made to produce a small sun with this light the chief working quality of that light—its economy—was sacrificed. He admitted that it had been claimed for several systems at work that they solved the difficulty of subdivision without sacrificing economy; but he maintained that their success was doubtful. The only direction in which we could move with any chance of substantial success towards making electrical illumination generally practicable was in that of abandoning the arc altogether and going to incandescence pure and simple. The process of incandescence a small enough light could be produced for domestic purposes, and it could be divided indefinitely. With a constant current the same amount of light was then obtainable at any part of a wire, whether it was short or long, and the one condition to be observed towards the maintenance of a constant current was the reduction of the electro-motor force in proportion as the length of wire varied.

That there were practical difficulties to be overcome in the application of the incandescence principle was fully recognized, but Mr. Swan considered those were neighter numerous nor insurmountable. He showed that those were neither numerous nor insurmountable. He three chief sources of failure were—that due to the carbons being so thick as to require a very strong and, therefore, expensive current in them, that due to the non-durability of the carbons employed, and that due to the lamps specially becoming blackened or obscured. He stated that 20 years ago he tried to overcome these difficulties, and to produce an electric light by the incandescence of carbonised paper in a lamp from which the air was exhausted, but owing to the less perfect appliances of that day the result was not satisfactory. The discovery

of the dynamo-electric machine, which has been constantly referred to in the *Mining Journal* in connection with the economic production of electric currents since the machine of this case, exhibited by Mr. Wm. Ladd at the Paris Exposition in 1867, attracted so much attention; the invention of the Sprengel pump, and the experiments of Mr. Crookes in the production of a good vacuum led to fresh investigations, and enabled Mr. Swan to employ successfully the thin filaments of carbon which he now uses. He explained that the filaments with which his lamps were fitted were extremely thin—only about a hundredth of an inch in diameter; they were 3 in. long, and the bulb of the carbon filament weighed only one-fiftieth of a grain. The material was both hard and elastic, so as to be more like a wire than a carbon. The economy of the light to be obtained by the incandescence of this conductor was limited by its capacity to endure an enormously high temperature corresponding to a extreme degree of incandescence. The carbons were more durable when heated to a moderate degree than when the temperature was pushed to a high pitch. It was still an open question what was the most light to be obtained by such lamps, but he knew that a well-made lamp with a carbon of one-tenth of an inch total superficial area would endure for several months, if not pressed to give more light than 30 standard candles. As evidence of the character of his light, Mr. Swan showed 12 globes, each containing three of his tiny lamps, and he stated that each of the enclosed lamps was of the power of from 20 to 60 candles, explaining that his object had been to imitate gaslight, but to give as much light as possible.

As to the commercial value of the invention, no definite opinion can be formed until details can be obtained with regard to the composition, cost, and durability of the carbon; but when such men as Professor Ayrton, Mr. Varley, and Professor Tyndall express their satisfaction with the experiments, there need be no doubt that something is to be expected from the invention. Professor Tyndall said the question that remained to be decided was the durability of those extraordinary filaments of carbon, regarding which their curiosity was aroused. Small lamps of this kind might possibly be made of considerable use in coal mines. It was very easy to inclose small lamps of the kind in water so that they should be protected from the explosive gases of the mine. When the question of the durability of the carbon was settled Mr. Swan's success would be complete. Mr. Swan showed by actual trial at the meeting that an inexperienced person could fit a new lamp much more easily than an ordinary gas globe is fixed in its place. As to the durability test, he had been burning the same lamps since Aug. 3, with one interval of three weeks only. From these data it may safely be assumed that Mr. Swan has some means of the production of an electric lamp applicable in collieries than any of his predecessors, and if it be demonstrated by actual trial that 50 lights, each of 20 candle power, can be produced with 4-horse power indicated, there can be no question that Professor Tyndall's suggestion will be adopted, and that collieries will be economically and brilliantly illuminated by a method which will render the ignition of fire-damp, and consequent disastrous explosions, practically impossible.

Electrician Nov 27th 1880

MR. EDISON'S LAMP.—The Patent Museum, South Kensington, now contains Mr. Edison's "original lamp," accompanied by a certificate stating that it burnt for 1,300 hours.

FRENCH OPINION OF MR. SWAN'S LAMP.—*La Lumière Electrique* reminds its readers of its oft-repeated charges by it not replied from, Mr. Swan. Mr. Swan's recent lecture affords some occasion for rejoicing at the confirmation contained therein of its opinions, and although refraining from any definite views with respect to the practicability of subdividing the light indefinitely, *La Lumière* speaks very highly of our countryman's labours.

ELECTRICITY IN COLLIERIES.—In his recents letter to the *Times* Mr. W. H. Preece pointed out that lightning was probably the immediate cause of some colliery explosions, and alluded to the Risca explosion as a case of the kind. His statements were criticised by Colonel Shakespear, and in reply to this criticism Mr. A. H. W. Radcliffe has written the following the whole of last week prevented my earlier answer to Colonel Shakespear's letter in your edition of the 6th, and as I am the Mr. Arthur Radcliffe alluded to by Mr. Preece (in his letter to *The Times*) as having investigated the matter of the Risca explosion on the spot, I feel called upon to respond to Colonel Shakespear's query as to my having charge of lightning, assuming it stands to the credit of which I prefer to take the course down the shaft in preference to the mass of metal in the engine house. In the first instance the engine is generally well insulated by having a solid bed of masonry or concrete for its foundation. In addition to this, at Risca the engine house is built at the side of the mountain, which is almost wholly composed of stone. At all events, wherever the shaft has slipped or been removed near the pit, scarcely anything but stone is apparent. And my experience as telegraph engineer for the Monmouthshire Railway Company, which runs by the colliery and through adjacent valleys, has shown me the difficulty of obtaining what is technically known as 'good earth' in such ground. In the collieries in the neighbourhood I have had to carry my earth wire several hundred yards; therefore it is only reasonable to assume that the conducting ropes and rods down the shaft, terminating in long lengths of metal rails, would afford a better channel for escape than the mass of insulated metal in the engine house. With reference to Colonel Shakespear's further remarks as to the engineman not having spoken on the subject, he did so on the day of the explosion; he said a flash appeared to strike the building, and a few seconds afterwards the explosion occurred. Whether this flash caused the explosion or not is a matter that must now be one of opinion only. Mr. Preece's object in writing his letter was merely to call attention to a very possible source of danger, which could only be avoided by having the head gears of collieries thoroughly protected by lightning conductors—not such as are usually fixed by rule of thumb—the end of the rope simply buried in the ground, regardless of the nature of the soil—but by conductors efficiently fixed and electrically tested. In vindication of the theory I propounded to Mr. Preece, and which produced his letter, I may say I had it personally from one of H.M. inspectors of mines that a manager of a colliery mentioned to him that some of his men have been very much alarmed at seeing a flash of lightning on the metals underground during the time a storm was raging overhead. What would have been the result in that case had there been gas present?"

REMINISCENCES

COMMERCIAL SKETCHES.

OLD PHILADELPHIA AND SOME OF HER MERCHANTS.

No. 6.

"LAMARTINE wrote that "it is not requisite one should be a great man in order to be a great king." True, and so of life generally. A man may be a great thinker without developing much of anything to himself, either himself or his fellow-men. Another may be a great administrator and yet be incomprehensible in all else. A great army officer may be a very mean man, or little-minded in everything that does not pertain to his particular pursuit. The author's idea of a great king was doubtless that he should comprehend fully the duties of his exalted vocation, and that so comprehending he would govern with breadth of vision, and that so comprehending he would govern with wisdom, justice, and humanity. Great fortunes are frequently made by men of very ordinary capacity or acquirements. Little men often pursue a single idea, or elevate their whole lives to the pursuit of gain in a beaten track, and thus accumulate wealth at the sacrifice of every duty that is imposed upon them by society and indeed by their fellows; but a great merchant is endowed with skilful capacity, acute discrimination, and farseeing judgment. Although not intuitively great he becomes a great merchant by the careful exercise of such powers. Greatness is the result of combination. Great storms arise from a combination of the elements. Great parties are formed by combining large numbers of men together, as are great armies, great fleets, great cities, and great countries, in which are embraced all the elements of population and civilization generally.

Among the most notable houses in our city, or indeed in the United States, engaged in the foreign trade fifty years ago was that of the Browns. The original house was established in Baltimore by Mr. Alexander Brown. After a very successful career as a merchant in the Monumental City, Mr. Brown associated with himself his three sons, and established branch houses in Philadelphia, New York, and Liverpool. In this city the firm style was John A. Brown & Co., and in New York that of Brothers & Co., Mr. James Brown being the managing partner. In Liverpool it was William and James Brown & Co., the first-named partner being the manager, while in Baltimore the firm name was changed to Alexander Brown & Sons; and thus was launched into the field of trade and commerce what in after years became a great financial power on two continents. The business of this combination of firms was a general commission trade and dealing in foreign exchange. During the cotton shipping season they had an agent or representative of the house stationed at each of the cotton ports, who bought from the planters or shippers the drafts that were drawn on England against shipments of the staple, paying therefore in cash or sight drafts on their Philadelphia or New York house as desired. The bills purchased at the cotton ports were sent to the house in this city or New York, and thence forwarded to the Liverpool branch for collection and thus John A. Brown & Co. were always ready to furnish to the importers of our city any amount of English exchange that might be required for remittances to pay for goods purchased on the other side of the ocean. The business of the house in this connection was for many years simply enormous, and must have been extremely profitable.

The unsettled and precarious condition of domestic exchange at this period, when every State had its own system of banking, some of which was of the "wildest" order, and when it was frequently difficult to buy a dinner notwithstanding one had an abundance of money so-called, must have contributed largely to the success of the Browns, and a recurrence in the experiences of that period suggests that after all the rebellion of the Southern States has not been without substantial benefit to the whole country. Up to the year 1861 the currency was phenomenally bad; now, under the national banking system, which was forced upon us by the exigencies of the war, it is the best in the world. With this admirable system in operation throughout the entire country, a note issued from any one of our Philadelphia banks is as good in New Orleans, San Francisco, or anywhere else as it is here. Not even the "All United States Bank, with its branches in various localities, was able to accomplish half so much. Under the present system, as is well known, the security to note-holders is so absolute that the issues of a bank that may from any cause have failed are worth as much as those of a perfectly solvent one.

The business place of the Philadelphia branch of this great commercial establishment was originally on the south side of Chestnut Street near Front. In later years it has been in the same building with the National Bank of Commerce, in which institution the firm is largely interested. The original members of the firm have all, we believe, been retired to their mansions whence no traveller returns, but the business has been continued up to the present time by the younger branches of the family. The first change of firm name of the Philadelphia house was when it was altered to Browns & Bowen, and then to Brown Brothers & Co., which it bears at the present style. The Liverpool firm was meantime changed to Brown, Shipley & Co., and is still so continued, a London branch having been established within late years under the same firm style.

Mr. John A. Brown, the old-time chief of the Philadelphia house, died some years ago. He illustrated the idea with which we introduced this article. Of a quiet, unobtrusive, and genial nature, he was not at all a great man, but he must have been a great merchant to have conducted successfully the affairs of a firm that was during many years of his life so conspicuous, not only in our own but in other countries. For many years he was a director of the Insurance Company of North America, and at times also of different banking institutions. Being of retiring habits he confined himself strictly to business and the care of his family. He accumulated a large fortune, and at the time of his death was said to be worth three to four million dollars, and yet we recall an incident in the history of the firm which for a time threatened to be more disastrous to the monetary results to all its members.

It was at about the year 1848 or '49 that one of those semi-periodical panics which have from time to time wrought financial wreck and ruin took place. It affected England and America alike. Old houses that for many years had been considered impregnable were shaken, and tottered as though they must fall before the sweep of the hurricane, and many, the proprietors of which considered themselves invulnerable, went down, and the debris of years of commercial enterprises and thrift was being strewn about like driftwood, not only in the United States but in Europe. It so happened that the Liverpool branch of the house was much extended at this time, and its assets were daily and hourly being loosened. Crumbling away under pressure of the panic they were becoming almost entirely unavailable as cash resources, and as a consequence the position of the house had become extremely critical. Every effort had been made to ward off the impending evil, and as a last resort the last expedient was resorted to by the Bank of England for relief and assistance, and Mr. William Brown, the senior member of the Liverpool firm, who, by the way, served some years as a member of Parliament, went up to London to meet the directors of the bank, and under the necessary application. The condition of the house was set forth, and its entire solvency was shown, provided temporary aid was afforded. Mr. Brown waited tremblingly and with impatience an entire day for the decision, and finally it was received in the shape of a negative, and which filled him with apprehension he returned to Liverpool and reported the failure of his mission to his partners. Among these was Mr. Joseph Shipley, a young gentleman, then of great energy and enterprise, one of those Englishmen who don't admit the word fail into their vocabulary, and justly proud of the standing of his firm he expressed himself as highly indignant at the bank's refusal, and declared his purpose to proceed at once to London and renew the application. He would see, he said, if the directors there to refuse an application that was so legitimate, and at the same time reasonable. "They shall do it yet," he added, "notwithstanding their refusal," and he took post at once for London. His first business was to get the managers together again, and this done he appeared before them in person, and related the case with such cogency of argument that ere the day had closed the board was induced to change its action and grant the needed succor. And thus was this great commercial and financial establishment saved from impending bankruptcy. If the Liverpool house had fallen the others must have gone down also, and thus would have been wrecked the several splendid fortunes that had been realized by the respective members of the different firms. Mr. John A. Brown was greatly alarmed on account of the ruin with which he seemed to be threatened, and looking only at the darkened side of the situation he was wellnigh in despair. And so greatly was he excited in regard to the matter that it was said at the time, and we believe truthfully, that he proposed to some friends that if they would secure to him an annuity of six thousand dollars a year during life he would transfer to them his entire interest in the firm. Such are the mutations of life, and such the changing vicissitudes of trade and commerce, that the millionaire of to-day may become the mendicant of to-morrow, and the servant, as it were of yesterday may aspire to be the assistant of the coming hour.

shore end, and not far from it, and added it upon the 22nd. The wire was first case of a cable breaking down and then being repaired.

In this same year (1850) a cable was laid by Messrs Newall, at Sunderland, was laid across the belt for the Danish Government. It had three conductors of No. 16 copper covered with gutta-percha, and was 7 miles in length. It was laid by Mr. Robinson from a schooner in the employ of a tug, and is the first example of laying a cable from a moving ship in tow. In November of the same year the author laid a cable of exactly the same pattern across the Solent from Cowes to Hamble cutter, with her mast removed, in tow of a tug. In December of this year the author laid from the "Monarch" a cable across the Firth of Forth and River Tay. The pattern of these cables was four copper cables laid up together in a similar manner to the ordinary shore-ends of the Hague cables.

1854. In May of this year, the "Monarch" was chartered by Messrs. Newall and Co. from the Electric and International Telegraph Company, and a machine was designed by Mr. Newall placed on board. It consisted of two drums about seven feet diameter, with grooves 4 inches wide and about the depth of half the diameter of the cable. These drums were driven by a pinion working into another wheel on the drum shafts. Bow bunks were fitted with a bow sheave about six feet diameter, with wrought iron spokes. The bunks projected beyond the sheave, and a bollard at the cable in between, but no check gear either at the bow or stern was used. With this machinery the 10 miles of Portpatrick and Donaghadee cable were recovered by Mr. Newall. The exact date of this expedition the author has lost, but it forms the first example of picking up a cable and the machine having two drums with grooves ins—ver been since employed for picking up from the bottom. The next year of the 1854 machine was a modification as regards two grooved drums. On October 6 of this year the single cable picking-up gear, with knife to cut the cable, designed by the author, was fitted by Messrs. Jackson and Amos, was fitted on board the "Monarch." A drawing of this machine is given in the author's paper, read before the Institution of Civil Engineers on 22nd February, 1859. It is the first example of a picking up machine with a cutting knife. It had also a ratchet, and could be worked by manual power, long handles extending on each side of the driving shaft to tackings on the gunwale of the vessel, and thus about thirty men could be applied to it. Steam power was applied in the next year, as the work got heavier.

On September 4 of this year a cable centrally similar in type to the Hague cables was laid between Holyhead and Howth, from the "Monarch," the break being picked up by the "Elfin." The expedition was under Mr. E. Clark, assisted by the author.

SWAN'S LAMP AT THE SOCIETY OF TELEGRAPH ENGINEERS.

A very large gathering took place at the Society's rooms, Great Georgestreet, Westminster, on Wednesday evening last, in order to listen to Mr. Swan's exposition of his new electric lamp, and to witness its performances before a professional audience. Sir W. H. Preece, the President, occupied the chair, and amongst those present we noticed Messrs. Latimer Clarke, Cromwell F. Varley, Sir C. Bright, Professor Abdank, Mr. Spagnoletti, Professor Carey Foster, Professor Ayrton and Perry, Mr. Shelford Bidwell, Mr. Preece, Mr. Sabine, Mr. Culley, and a number of many others well known in electrical and scientific circles. Various specimens of the lamps, exposed as well as enclosed, were suspended overhead, and one occupied the interesting position of being a substitute for an ordinary table lamp. These were all lighted later on in the evening, and remained burning to the end. We will describe them fully as we proceed.

Before introducing Mr. Swan, the President announced that the trustees of the Siemens Gift had made the investigation of the subject over, and had expressed their opinion that everything had been done in accordance with the conditions of the bequest. Arrangements would shortly be made, it was hoped, for opening the library not only to the members of the Society, but to the general public under certain conditions, and a proposition would be submitted to the members very shortly for carrying out this intention.

Mr. Swan, who was very warmly received, began by remarking upon the, as he thought, useless attention that had been given to lighting by means of the electric arc, and the more familiar method, as he say, the working of a continuous conductor, having been very little considered, at all events, in this country. Theoretically there was no question as to the superiority of the last-named mode of lighting, especially where a number of lights were required, and the more familiar method, and he was long ago convinced that incandescent lighting was the only and only form of popular light possible, if popularity was to be won for any system of illumination by means of electricity.

Arc lights, it was obviously limited. It can only be employed in large areas, for to attempt to use it where the space is small would be to waste the excess of light extravagantly, and to attempt to split it up into smaller lights, still of the arc pattern, by applications on the score of cost became only as he saw her in his enthusiastic youth. Nor [illegible] to the handkerchief decked with royal lace. The accounting now were serious. These objections applied even to the Wiesbaden and Regular lamps, although they were decidedly soothing, as regards the latter, on the other hand, they did not possess the steadiness of the Jablochkoff candle. Mr. Swan then discussed in detail his regret that the question of arc lighting was still kept very much in the dark, and that at the recent competition at Glasgow, from which so much was expected, only one lamp (Sir, Crompton's) held the period of an incandescent lamp. In the absence of figures, therefore, Mr. Swan observed, regarding the cost of producing arc lights, we have only inexperience, and the impression conveyed to the minds of most observers was that the biggest light was the cheapest. Mr. Swan noted, that a very big light was [illegible] 2,000 candles, gave 25 twenty-candle lamps and 2 arcs of 1,000 candles. On the other hand, the standards worthy of the name of arc lights, and the expenditure of candles and time of renewing them, skilled attendants being required to periodically attend to them. Then again, the question of the management of the current had to be encountered in one spot, not merely distributing very rapidly in strength as it extended, but by the very laws of nature, it was the reverse use of the term; "candle power." As is well known, this term is highly elastic, and upon its use or abuse a great many unfair statements have been based.

However, Edison almost universe connected with the Brush system of lighting to show that at any time, or under any conditions whatever, the Brush light, rated at 2,000 candles, ever approached one-fourth of the power of the single light, given by the A Crompton machine, which he (Crompton) valued at 4,000 candles. I will go further, and state publicly that had not the Brush system been withdrawn from the competitive trials at Glasgow, the fact would then have been made patent to the world that, under equal conditions of measurement—if 1 h.p. used in the Gramme system gives the light of 1,000 candles, 1 h.p. used in the Brush system gives the light of 1,000 candles only. These figures may be increased or diminished, but the proportion between them remains as above.

The facts and figures are really far less favourable to the Brush system than this, but I have preferred to keep on the safe side.

If these figures had been applied to the estimation of candle power in the City tender, the Crompton system would have been found to be far cheaper than the Brush for equal light supplied.

—Yours, &c., W. CROMPTON.

Mansion House-buildings, Queen Victoria-street,
November 24, 1880.

1852. Specimen Lamps: A. M. Clark, London. (C. F. J. Gravel-Lacroix, Paris), for 1 light, the chief improvement consists in the arrangement of the electrodes, which are placed in a vertical position, the positive above the negative, and in such a way that the latter is constantly pushed up by its own weight. The lamp is composed of two pairs of tubular carbon holders at right angles to each other, the one set of carbons [illegible] with the holders and mechanism is mounted on a frame [illegible] being thereof to it at a permanently fixed distance.

The arc electric-current carried in a shunt circuit, and serves to bring the carbons together to establish the arc, the spring A acts upon the upper carbon holder, and tends to separate the carbons, but by the pressure exerted by the electro-magnet B, which is in series with the main current passes, carried principally by the coil C, the carbons are kept at a distance from each other, the arc being thereby established. (Jan. 23, 1880.)

ENGINEERING. Nov 19

ELECTRIC LIGHTING IN THE CITY.

On Tuesday last a meeting of the City Commission of Sewers was held to consider the tenders submitted for lighting during one year three districts of the City, in answer to the requirements of the Act. The offers from tenderers were considered. The first four different systems were considered. The first district comprises Blackfriars to Hill, the north side street, Ludgate Circus, Ludgate-hill, and Cheapside as far as St. Paul's Churchyard, and Cheapside as far as King-street. The particulars of the tenders for this district were as follows:

—	Qnty. for 25 Lights.	Fitting and erecting.	Total.	Number of Lights.	Yearly Cost.
Crompton ...	£ 2375	£ 600	£ 2975	25	£ 119
Siemens ...	2000	1000	3000	25	120

The Siemens' lights will consist of 20 small and six large arcs. The Brush system of 16 small arcs awarded to Messrs. Siemens Brothers. Some idea of the different kinds of installations proposed may be gathered from the following particulars. The Anglo-American Lighting Company will erect lamps on separate posts, not less than 13 ft. above the ground. Overhead wires will lead from the company's Victoria Works, Vine-street, Lambeth, where the power will be derived, and from this post to post, overhead, except across the streets, when they will be carried underground. Messrs. Crompton and Co. suggested employing lamps capable of sliding up and down posts, or suspended across the streets, and to be lowered by cords and pulleys. Upon the bridges the lamps would have been carried on posts 25 ft. high. The Electric and Magnetic (Jablochkoff) Company will erect lamps on same system as on the Embankment, the wires being hung from lamp to lamp, and carried over the crossings, on high posts. Messrs. Siemens Brothers will employ large lamps in clear glass globes, with sawdrella-shaped reflectors, placed on posts 70 ft. or 70 ft. high, and mounted on the parity or wholly frosted clear globes, on 20 ft. standards. The wires will be laid underground, and the light-producing plant will consist of two 10-horse power semi-portable engines, three medium-sized dynamo-electric machines, and the siliconate current machines, with their sections. In making their report and recommendations, the Street Committee stated that they had been guided not only by the prices given in the tenders, but by the effect produced with the different systems in actual operation, all of which they had seen.

Do not photograph on this side

RECENT HISTORY OF ELECTRIC LIGHTING.

BY HENRY MORTON,

President of Stevens Institute of Technology.

On the 17th of October, 1878, in fulfilment of a promise made a year before, the present writer read before the American Association of Gas Engineers an address in which (alluding to the reports then resounding in the daily papers as to Mr. Edison's new form of electric lamp) he said, after quoting an account of a similar report current twenty years before in France: "These promising experiments, as we all know, reached no successful results. I would by no means, however, have it inferred that better success can never be attained. On the contrary, there are several very promising directions for experiment, on one of which no doubt Mr. Edison is at present embarked; but the difference between a promising line of experiment and a successful result, as all the world's history teaches us, is often a distance of many years, to say the least." An opinion so little calculated as this, to aid in "bearing" gas stocks, naturally excited no little disgust in certain quarters, and I had the pleasure of seeing myself very handsomely abused by those whose approval would have been a very doubtful compliment.

Looking back over the space of two years which has elapsed since those words were uttered, and remembering the events which have transpired in this connection, I feel that I have much more reason to congratulate myself than have those who took an opposite view.

Not only has "the promising line of experiment on which Mr. Edison was then engaged been separated by many years from a successful result," but it has, within this time, been totally abandoned by him, without, so far as known, either to say the least, still under approval, and the discredit and difficulties which has been cast from all sides, has shown how unfortunate and unwise were the reckless and unfounded assertions of the would-be Prophets of the Press.

Notwithstanding these draw-backs, however, continued progress has been made in the development of the art of lighting by electricity, and we have to regret that would otherwise have been a dignified march of advancing science, reflecting nothing but credit upon this country and its inventors, has been perverted to some extent into a carnival rout of grotesque and absurd extravagance.

In recording the progress which has been made in the art of electric lighting, the most important practical results have been achieved by those who have devoted their attention to the application of the electric arc, the peculiarity which presented itself two years ago in this subject, was the unsteadiness of the light, its great liability to extinction, and the extreme difficulty of maintaining it. By improvements in the carbon rods as to their purity of composition and uniformity of structure, a great increase in steadiness has been attained, and by other improvements in the mechanical arrangements of the self-adjusting lamps, this amelioration has been likewise assisted.

Among those who have done most for the improvement of the carbon rods, I would mention Wallace & Sons, of Ansonia, and among the most marked improvements in electric lamps, I would cite those of the Brush Co., of Cleveland.

The economical efficiency of the electric generators or dynamo-electric machines, has also been increased, and in this regard the best results, so far as accurate tests which have been published indicate, have been obtained by Mr. Siemens' machine, as tested by Profs. Young and Bracket, shows the very high efficiency of 84.1 per cent. of motive force or energy converted into electric current. The machines of other inventors appear to be only a few per cent. behind this, if indeed some of them are not found to equal it when accurately measured.

In consequence of these improvements and of the energy with which the several manufacturers have brought these machines to the notice of those likely to use them, their employment in factories, stores, workshops, and hotels, has become very general, and has undoubtedly proved of great advantage and convenience, although instances are not wanting (as for example in the great cotton mills at Lowell, Mass.), when the electric lighting was abandoned after a thorough test.

There is, however, so wide a field in which this light has manifest advantages over any other means of illumination that we may confidently look for a vast increase in its introduction in all parts of the country.

Turning next to the production of light by incandescence we find that this branch of the art also has made marked advances. This art had its beginning as early as 1845, when in the patents taken out in England by King, the representative of the American, Mr. Starr, we find described the use of platinum wires and thin rods of carbon, the latter inclosed in a torricellian, or absolute, vacuum. Extensive experiments in the same line were made by Mr. Moses G. Farmer, the widely known electrician, about the year 1858 and again a little later, by Dr. Isaac Adams, the inventor of the process of nickel plating, now widely used; but the costliness of an electric current derived from a galvanic battery prevented the earlier experimenters from reaching any commercial success, and even with the cheap electricity of to-day, there is still a limit set upon this sort of lighting, by its relatively wasteful expenditure of electric force and consequent costliness.

Great progress has, however, been made here also.

Mr. Edison supposed he had solved the problem two years ago when he had re-invented the earlier methods of Starr, Farmer, and others, but very soon finding, as they had done, the insufficiency of his solution, he attacked the problem afresh with an energy, persistence and originality of resources worthy of all praise. The outcome of his researches he has brought to light a number of astonishing results, and has discovered whole classes of new properties in platinum, and other metals, and lime, magnesia, zirconia and other substances.

Had his enthusiastic friends only claimed for him from time to time what he had actually done, his fame would have been unclouded as a discoverer, and without blemish.

Unfortunately, too many prophecies have been indulged in, and the credit of really great achievments has been overshadowed by the failure of still greater assertions and promises.

After the abandonment of the platinum lamp, Edison next took up the carbon-horseshoe lamp of Starr, and as before, his friends shouted "Eureka" at the beginning and not at the end of his search.

The carbon lamp, as first made by him, has met the fate of its predecessors, and has been abandoned by him likewise; but from its ashes have arisen, lamb in his other hands, improved descendents, which show the significance of survival.

Having found it practically impossible to make his paper carbons sufficiently durable when heated to such an intensity as would render them even possibly economical as sources of light, he has ransacked nature for some material which would fill these hard conditions, and in a certain variety of bamboo has found something which he believes will yield him a fine hair-like thread of carbon with which he can obtain the light of 16 candles from a single lamp, at an expense of 3.400 foot pounds of energy a minute. This would represent about 9 such lamps, or about 155 candles per horse power.

This is a decided improvement in efficiency over his horse-shoe lamps of last year, and with a durability, as is claimed, of six months, will seem to some a long step forward on the roads toward success.

Starting, also, with the idea of Starr as to the use of a strip of carbon in a vacuum, Mr. Maxim has proceeded along a different road.

In place of searching through nature for a substance which would yield a perfect lamp-carbon on hunting, Mr. Maxim has sought to make a perfect carbon strip in his lamp by building it up on any imperfect form as a substratum. To accomplish this he has taken a strip of carbonized paper as his groundwork, has covered this over with a metallic layer of graphitic carbon, by heating the original carbon strip by a current in an atmosphere of gasoline vapor. Under these circumstances, we only is a sheathing over the strip, but, if there is a weak spot anywhere in it, the carbon will be thrown off at this point (on account of its getting hotter than the rest), and thus an irregular or defective carbon strip will be repaired and rendered perfectly uniform.

By this process two objects are attained. In the first place a good carbon strip is secured, no matter what imperfections may have existed in the original paper or other carbon foundation. In the second place, the outer surface of the strip is composed of that variety of carbon whose resistance to heat and mechanical injury surpasses all others. All familiar with the material will know, that what is technically called "gas carbon" (*i.e.*, the carbon deposited in the mouth retorts by the decomposition of the issuing gas), of gas is a metal-like substance, the cutting, breaking, or shaping of which is very difficult, on account of its combined hardness and toughness. It very rapidly wears the best steel files and saws, and to break it with a hammer is almost a hopeless undertaking.

I have also known a weighted quantity of it to be placed with the fuel in a cupola furnace where iron was being melted and to have been taken out again after some hours, not sensibly diminished in weight.

This is the material of which the surfaces of the carbon strips in the Maxim lamps are composed, and should they prove as durable as I have hoped, it is to this that we should naturally credit their resistance.

I have measured a number of these lamps with such results as the following:

Lamp A. Resistance cold 2.04 ohms. and when yielding in its best position the light of 50 standard candles its resistance was 8.3 ohms. The current required to heat to its degree was one of 4.07 webers, and the energy expended was therefore 33.8 volts. Ans four pairs of these lamps were about five and a half (5½) such lamps to each horse power of energy of current employed or an efficiency of about 220 candles per horse power.

Taking 70 per cent. of this as the average for all positions we would have about 192 candles per horse power of current. Now the amount of actual horse power in the steam engine required to develop one horse power in the lamps will vary with the dynamo-electric machine the number of lamps in use and other considerations, but we may assume 80 per cent. as a safe allowance and this would give us about 115 candles per actual horse power on the engine as the efficiency of this lamp when run at 50 candles.

Another lamp (D) when resistance cold was 115 ohms. when yielding a light of 52 candles required a current of 1.35 webers and had a resistance of 64 ohms, when emitting the above mentioned amount of light.

The electric energy consumed in this case was therefore about 2.131 foot pounds per minute or about 64.4 metre kilogrammes per minute.

Taking 70 per cent. as the average light in all directions, reduces this to 42.1 candles, and assuming 60 per cent. as the efficiency of the conversion from motive power into electric current in the lamp, brings it to 138 candles per horse power of mechanical force developed in the steam engine.

We see therefore in this case also a marked advance upon the best of the art a year ago.

Undoubtedly an advance now made is sufficiently encouraging to authorize the experiments which are being made to apply these lights on a practical scale in situations where they have

Electric Light. Mackinet 1880

Electric Lamps.

THE SOCIETY OF TELEGRAPH ENGINEERS.

An ordinary general meeting of this Society was held on Wednesday, Nov. 24th, Mr. W. H. Preece, president, in the chair. The minutes of the last general meeting having been read and confirmed, the President announced that at a meeting of the Council trustees it was unanimously agreed that the Society of Telegraph Engineers had fulfilled the conditions upon which Mr. Ronald's library was to be held by the Society. On the 22nd a general meeting would be held on which application for opening the library to the public would be considered.

Mr. J. W. Swan then read a paper on "A system of sub-divisible Electric Lighting."

Mr. Swan first referred to the lighting and lighters by the heating of carbon rods by the passage of the current, and showed that theoretically a light produced by incandescence was above all others very good; that this light is unquestionably economical when concentrated, but possesses great mechanical defects. The arc light is not of much use for small lights, not being economical.

Several systems of lighting by incandescence have been stated to have been successful, but such has not really been the case. Definite numerical data are wanting on the subject, since mere impressions are not sufficient to guide any one.

Mr. Swan then referred to Mr. Edison's system of electric lamps, which was described before the Society of Telegraph Engineers, and after giving the theoretical data of the light which threw some light upon the nature of the materials material employed for obtaining the illumination—"I have found that when the carbon employed while the lamp is in action is borrowed, shaped plate, produced by cutting out the arch or horseshoe-shaped piece from a sheet of cardboard, and afterward carbonizing it by heat, that the arch or horseshoe-shaped carbon so produced is found to become distorted and ultimately to break in consequence of the unequal contraction caused by the unequal heating of the inner and outer portions of the arch during the use of the lamp. This defect I remedy by forming the carbon to be made incandescent of a strip of cardboard or paper cut into the form of a loop or strip; the front view of such loop or loop showing the section or thickness of the strip, and the side view its width. *The strip of cardboard or paper used as aforesaid is subject to a while heat in a close vessel or retort containing powdered carbon or other suitable air-excluding powder.*

There are now 318 telegraph stations in England and its operations in the United States.

POLICE.—The corresponding Chicago leads the way in adopting improvements for protection of public peace. Electric telegraphic stations have been established at different points in one important district, and relays of mounted officers are kept in waiting at a central station. Reliable citizens are furnished with keys to the telegraph boxes to protect their residences. To prevent, false alarms the keys are numbered, and cannot be withdrawn from the lock until released by a key carried by the policeman on that beat. When anything goes wrong in a district the alarm is sent to the central station, and explanations are given through the telephone. In case of serious disturbance a large force is sounded, and every officer on post runs to the nearest box to receive orders.—*Scientific American.*

peculiar advantages, as for example in the vaults of the Safe Deposit Co., under the Equitable building in New York, and in some adjacent offices.

When that experiment has been carried on for a few months we shall know much more than we do now as to the actual running cost of the system, but anything like a general adoption of the same in place of gas is still an affair of the future about which prediction is premature.

Gas and Electricity.

Illuminating Power of Gas in New York City.

E. G. LOWE, Ph. D., *Gas Examiner.*

ERRATA.—The report of the illuminating power of gas in New York City, for the week ending Oct. 23, was erroneously stated. The average of the Metropolitan should have been 21.56; Mutual, 25.36; Municipal, 20.13.

The accompanying illustrations show two forms of heating apparatus, invented by Messrs. Ritchie & Co., and noticed in the *Metropolitan*. They are designed more especially for hot-houses, and doubtless answer this purpose well.

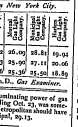

Fig. 1.

Fig. 1 is 3 feet 6 inches high, in which gas or oil may be burned, and consists of a central burner, placed within a glass tube. The products of combustion pass from the tube into a box at the top, and then down by the columns on either side. The object is to obtain the waste gases and vapors in a condensed form at the bottom. The condensed aqueous vapor will carry down with it most or all of the sulphur compounds, but a large part of the carbonic acid will escape. In a green-house, this of course is rather beneficial than otherwise, but if used in a dwelling, the carbonic acid would form quite a serious objection. Nothing is said of an escape flue, and we infer that there is none.

Fig. 2.

Fig. 2 is intended for lighting as well as heating, and has two burners on either side of a central column by which the products of combustion escape. It is 6 feet 6 inches in height; *Metropolitan* says that a burner consuming 3.4 cubic feet of gas per hour, and giving the light of 4.3 candles, will give the light of 22.1 candles in the Ritchie apparatus.

It must be a very poor burner or very poor gas that gives only 4.3 candles for 3.4 feet of gas. The only feature about the apparatus calculated to increase the amount of light is the reduction of the air supply by making the products of combustion pass downwards, and the arrangement with most gases would not give the necessary amount of air to the flame, if it could be made to work at all.

Much has been and will be said about the advantage of the electric light over gas in respect to the non-contamination of the atmosphere by the products of combustion. It is but natural that persons who have any grudge against a gas company should be very eager to magnify the great advantages of electricity over gas as an illuminating agent, but many of the objections urged against the one are to a certain extent to be found in the other. As to contaminating the atmosphere, Prof. Dewar, in a paper read before the Royal Society of Great Britain, showed very conclusively that as high as 12 and 13 grains of nitrous oxide per hour were produced by many of the electric lamps.

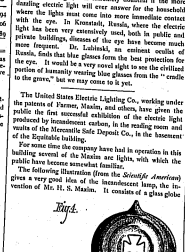
Buildings and rooms occupied by human beings or any other animals should be thoroughly ventilated, and it is certainly better to use gas with proper ventilation than electricity without it. The gas burners can be made to furnish the means for the ventilation of an apartment, and to persistently urge the "vitiating of the atmosphere" as an argument against gas is simply acknowledging our inability to establish proper ventilation. One might say, with almost equal force, that because the carbonic acid gas exhaled from the lungs vitiated the atmosphere that therefore we will stop breathing. It is not so important what our light is, provided it is adequate and suitable in other respects, as it is to remove the foulest air incident to all forms of combustion.

Another question which arises in considering the electric light from this standpoint, is the effect it is likely to have upon the eyes. In view of the many complaints which constantly come under our notice from persons using the yellow light of gas, it is extremely doubtful if the more dazzling electric light will ever answer for the household where the lights must come into more immediate contact with the eye. In Kronstadt, Russia, where the electric light has been very extensively used, both in public and private buildings, diseases of the eye have become much more frequent. Dr. Lubinski, an eminent oculist of Russia, finds that blue glasses form the best protection for the eye. It would be a very novel sight to see the civilized portion of humanity wearing blue glasses from the "cradle to the grave," but we may come to it yet.

The United States Electric Lighting Co., working under the patents of Farmer, Maxim, and others, have given the public the first successful exhibition of the electric light produced by incandescent carbon, in the reading room and vaults of the Mercantile Safe Deposit Co., in the basement of the Equitable building.

For some time the company have had in operation in this building several of the Maxim arc lights, with which the public have become somewhat familiar.

The following illustration (from the *Scientific American*) gives a very good idea of the incandescent lamp, the invention of Mr. H. S. Maxim. It consists of a glass globe



about three inches in diameter, in which is placed the thin carbon filament, and which is then filled with an attenuated hydrocarbon vapor; gasoline. Instead of using a glass globe it is closed by an elastic cement which resists both heat and pressure. The advantage of the hydrocarbon vapor is in the fact that as the current is passed through the filament, any defective parts become more intensely heated, the vapor is decomposed and the carbon deposited at the defective points.

The filament is either in the form of a Maltese cross, or like those in the Equitable building in the form of the letter M. By means of the button at the side, the lamp can be turned off or on. Mr. Edison, about a year ago, exhibited some lamps similar in some respects to those of Mr. Maxim. There was the same glass globe with the carbon filament, in the shape of a horse-shoe, but Mr. Edison attempted to produce a vacuum and then seal the globe by the fusion of the glass. Moreover, the carbon of the Edison lamp was destroyed in a short time. Mr. Maxim has constructed a current regulator which is a most important feature of this system of lighting by incandescence. By its means, it is claimed, the current in the lamp circuit is so regulated that any number of the lamps can be turned out without affecting the others.

In the reading room of the Mercantile Safe Deposit Co., which is about fifteen feet square, there are thirteen of these lamps, and the room is not brilliantly lighted at that. Mr. Maxim estimates that the large dynamo-machine will supply current sufficient for 200 of these incandescent lamps. It is also claimed that these lamps give a light equal to 20 candles.

At the recent meeting of the National Academy of Science in this city, Prof. Morton gave the results of some experiments with one of the Maxim lamps of high candle power. He found that when the conditions were such as to give a light of 12 candles, there was developed 12 candles per horse-power; when giving a light of 40 candles, 240 candles per horse-power; at 92 candles, 600 candles per horse-power.

To avoid the intensity of the light, the lamps are surrounded by frosted glass shades which considerably diminish the amount of available light. There is also noticed a changing in the intensity of the light, produced by the motion of the engine. This is seen when reading by the light, and as it is not obviated by the glass shade, it will sooner or later cause complaint.

They are said to be steadier than gas lights. If we look at the gas flame, protected by an ordinary shade with large opening at the bottom, we do notice more motion in some parts of the flame, produced by currents of air, but the body of luminous material is much steadier, and if one attempts to read by gas and then by the incandescent lamp, he will find that the light which falls upon the paper is steadier in the case of gas than in that of the lamp. On the whole, however, the new-comer must be considered the most successful incandescent lamp yet produced.

Mr. Edison claims that the Maxim lamp is an infringement of his patents, and that the United States Co. will not attempt to introduce it. Dr. Draper, however, proposes to light his house with the new lamp, which will be the first private residence in the city lighted by electricity.

At present the Electric Lighting Co., with which Mr. Maxim is connected, are very busy filling orders for the arc lights for out-door purposes, etc., but before long we may expect to see a thorough and extended trial of the new lamps.

Mr. Sawyer has been able to make an exhibition of his electric lamps in the Mercantile Library in Philadelphia, and the local newspapers speak highly of the results of the experiment. Five lamps were shown, the electricity being supplied by an Armour & Hochausen machine.

The lamp, it will be remembered, consists of a glass globe about ten inches high and two and one half inches in diameter, charged with nitrogen gas. In it there is a pencil of carbon one-sixteenth of an inch in diameter and about three inches long, which is pressed against a cylinder of carbon, one-eighth of an inch in diameter, by means of a coil spring. The carbon pencil is rendered incandescent for about three-eighths of an inch, and as it is consumed the spring pushes the pencil up from below. The lamps are calculated to burn about three hours, when they will have to receive new carbons and be recharged with nitrogen.

The cost of the small lamps is about $5, and Mr. Sawyer claims that the running expenses will be about 50 cents per day, but in most cases of this kind the lamps are owned by the company furnishing the power and rented. The larger lamps, giving a light of from 200 to 300 candles, will last from one to three months, and require one horse-power for two lamps, according to the inventor's claims.

It does not seem probable that any incandescent lamp will find favor which needs the constant attention which the Sawyer lamp demands.

An assessment of $60 per share has been levied on the stock of the Edison Electric Light Co., to cover $180,000 advanced by some of the larger stockholders for the purpose of experiments.

RECENT HISTORY OF ELECTRIC LIGHTING.

BY HENRY MORTON,

President of Stevens Institute of Technology.

On the 17th of October, 1878, in fulfilment of a promise made a year before, the present writer read before the American Association of Gas Engineers an address in which (alluding to the reports then resounding in the daily papers as to Mr. Edison's new form of electric lamp) he said, after quoting an account of a similar report current twenty years before in France: "These promising experiments, as we all know, reached no successful results. I would by no means, however, have it inferred that better success can never be attained. On the contrary, there are several very promising directions for experiment, on one of which no doubt Mr. Edison is at present embarked; but the difference between a promising line of experiment and a successful result, as all the world's history teaches us, is often a distance of many years, to say the least." An opinion so little calculated, as this, to aid in "bearing" gas stocks, naturally met with little disgust in certain quarters, and I had the pleasure of seeing myself very handsomely abused by those whose approval would have been a very doubtful compliment.

Looking back over the space of two years which has elapsed since those words were uttered, and remembering the events which have transpired in this connection, I feel that I have much more reason to congratulate myself than have those who took an opposite view.

Not only has "the promising line of experiment on which Mr. Edison was then engaged been separated by many years from a successful result," but it has, within this time, been totally abandoned by him for another, which other, to say the least, still under approval, and the discredit and ridicule which has been cast from all sides, has shown how unfortunate and unwise were the reckless and unfounded assertions of the world-de Prophets of the Press.

Notwithstanding these draw-backs, however, continual progress has been made in the development of the art of lighting by electricity, and we have to regret that what would otherwise have been a dignified march of advancing success, deserving nothing but credit upon this country and into a carnival rout of grotesque and absurd extravagances.

In recording the progress which has been made in the art of electric lighting, the most important practical results have been achieved by those who have devoted their attention to the application of the electric arc. "The word ARC . . ."

[illegible] have brought these machines to the [illegible] those likely to use them, their employment [illegible] tories, stores, workshops, and hotels; had very general, and has undoubtedly proved advantage and convenience, although it [illegible] are not wanting (as for example in the gr[illegible] ton mills at Lowell, Mass.,) where the [illegible] lighting was abandoned after a thorou[illegible] There is, however, so wide a field in wh[illegible] light has manifest advantages over any [illegible] means of illumination that we may con[illegible] look for a vast increase in its introduction [illegible] parts of the country.

Turning next to the production of light [illegible] candescence we find that three branch[illegible] also has made marked advances. In this a[illegible] its beginning as early as 1845, when the [illegible] taken out in England by King, the represen[illegible] the American, Mr. Starr, we find described [illegible] of platinum wires and thin rods of carbon [illegible] ter inclosed in a torricellian, or absolute, [illegible] Extensive experiments in the same line we[illegible] by Mr. Moses G. Farmer, the widely kno[illegible] trician, about the year 1858, and again [illegible] later, by Dr. Isaac Adams, the inventi[illegible] process of nickel plating, now widely us[illegible] the continuance of an electric current thro[illegible] a galvanic battery prevented the carbo[illegible] filaments from reaching any commercial [illegible] and even with the cheap electricity of [illegible] there is still a limit set upon this sort of [illegible] by its relatively wasteful expenditure of [illegible] force and consequent costliness.

Great progress has, however, been m[illegible] also.

Mr. Edison supposed he had solved [illegible] ten two years ago when he had recourse [illegible] earlier methods of Starr, Farmer, and o[illegible] very soon finding, as they had done, th[illegible] ciency of his solution, he attacked the [illegible] afresh with an energy, persistence and [illegible] of resources worthy of all praise. The [illegible] of his researches he has brought to [illegible] of astonishing results, and has [illegible] whole classes of new properties in plat[illegible] other metals, and lime, magnesia, zir[illegible] other substances.

Had his enthusiastic friends only [illegible] him from time to time what he [illegible] done, his fame would have been supp[illegible] a discoverer, and without blemish. [illegible]

Unfortunately, too many promises [illegible] indulged in, and the credit of really g[illegible] merits has been overshadowed by the [illegible] still greater assertions and promises.

After the abandonment of the plat[illegible] Edison next took up the carbon-[illegible] of Starr, and as before, his [illegible] "Berichte" at the beginning of [illegible]

[illegible] Edison's lamp consists of a [illegible] [illegible] about 2 inches in length; *Metropolitan* says [illegible] a burner consuming 4 cubic feet of [illegible] per hour, and giving the light of [illegible] candles, will give the light of 10.1 can[illegible] in the Ritchie apparatus.

It must be a very poor burner or [illegible] poor gas that gives only 4.3 candles [illegible] 5.4 feet of gas. The only fair test [illegible] the apparatus calculated to [illegible] amount of light is the reduction of [illegible] air supply by making the products of co[illegible] bustion pass downwards, and this [illegible] gases would not give the necessary [illegible] flame, if it could be made to work at [illegible]

peculiar advantages, as for ex[illegible] of the Safe Deposit Co., un[illegible] building in New York, and [illegible] offices.

When that experiment has [illegible] a few months we shall know [illegible] do now as to the actual runnin[illegible] tem, but anything like a great [illegible] same in place of gas is still as [illegible] about which prediction is pre[illegible]

From Nov 26 1880

The Exhibition of the Electric Light.

The new system of electric lighting by the incandescence of filaments of carbon was shown and explained by the inventor, Mr. Edison, at Newcastle-on-Tyne, on Thursday evening, before a large audience, in addition to the electric lighting apparatus already in use. Mr. Edison's system is peculiar in the method of subdividing the electric current, for which purpose he employs a battery of small cells. Professor Tyndall, who was present, described the system as one by which the electric current could be greatly subdivided, and the light of the carbon could be greatly increased.

Clarence, Mr. Swan's success was complete.

TECHNICAL EDUCATION.—The London Company have arranged for a course of lectures being delivered, or papers read, at the hall of the company during the ensuing winter season. The course will consist of four lectures or papers upon subjects intimately connected with the materials used in the manufacture of cutlery, the 4 times to take place on the following dates:—Second ay, December 1st, 1880; Wednesday, January 5th, 1881; Wednesday, February 2nd, 1881; Wednesday, March 2nd, 1881. Sir Henry Bessemer, C.E., F.R.S., has promised to commence the course with a lecture on Wednesday, December 1st, 1880, on the Manufacture and Uses of Steel, with Special Reference to its Employment for Edge Tools." The admission will be entirely free, but by ticket, which may be obtained on application to the hon. secretary, addressed to the Cutlers' Hall.

American Machinist Dec 11 1880

The Latest Electric Lamp.

Arrival and Trial.

The Maxim lamp, which is mentioned as accomplishing the results sought for by Mr. Edison, is an incandescent lamp, having a filament of compressed carbon, which is placed in a glass globe from which the air has been exhausted and replaced by the vapor of gasoline. The carbon is a very weak point or thin part in the carbon filament when the current is passed through it, this part of course will become hotter than the rest, and will decompose the gasoline so as to deposit carbon in the form known as compressed carbon upon that particular spot. When this spot has been built up to an equal conducting power with the rest of the filament, the current from the machine is increased with the effect of making not the weakest point or thinnest part, and repeating the process just described. In this way the filament becomes gilded with gas carbon. The gasoline is then withdrawn from the globe, and the lamp is ready for use.

The claims are that the carbon will last for 1,000 hours, and the reason may be continued, that the City is a dwelling, the carbonic acid would form quite a serious objection. No escape for, and we infer that there is

Fig. 2 is intended for lighting ga[illegible] as bearing, and has two burners on [illegible] side of a central column by which [illegible] products of combustion escape. It is [illegible]

Edison's lamp consists of a [illegible]

Electric light is very perfect. The light is very steady, and the eye is not fatigued by looking upon it. The cost is as against the present Gas and Electric Light Company, and gives the rest as are: Gas, 10s. 6d. per 1,000 cubic feet; Electric Light, 1s. per lamp per hour. Another consideration from

1527. "Electric lamps." C. G. Arnold. Dated April 13, 6d. In electric lamps in which a stick of carbon is made to "burn" in a closed vessel or globe, the atmosphere contained therein, when the current is turned on by the current being cut off, consists of carbonic oxide and nitrogen. Owing to practical difficulties, in the way of making joints, it is generally found that the atmospheric air, while the lamp cools down, slowly enters the globe, and the atmosphere therein then consists of carbonic oxide mixed with oxygen and nitrogen, forming an inflammable mixture, which, when the lamp is relit causes an explosion and set a destruction of the globe, and sometimes also the interior parts of the lamps. The objects of this invention are to prevent the above evil, to regulate the consumption of the carbon as desired, and, as regards the point of the carbon, by incandescence, to preserve through the sole or cover plate, A, of the lamp, and the size of this hole is more or less according to the size of the carbon with a small quantity of air sufficient to preserve its form, and to burn the carbon dust thrown off, or nearly so. This aperture may be of desired, be made adjustable by being increased in size, and fitted with a somewhat conical screw, or one having one or more taper flats, which are broadest at the end and filed on it (like a tap for forming screw thread in nuts), or in any other suitable and well known manner. The tube, B, for the carbon and the weight resting thereon is narrowed at the top at A. C is an iron cup or tube valve, which is free to slide on the tube, b; it has a leather washer, c, beside the top, and has one or more holes at c the cup rests on the flange, a^2, on the tube, b; it is an insulating washer. As long as the current is not on, and the lamp burning, the cone tube, C, is down, and the leather washer, c, then rests on the top of the tube part, A, preventing air escape or entry at this place, but as soon as the lamp goes out, the current ceasing,

Fig. 1.

thus prevented; e is a helical spring for raising the cap tube, or valve, C, when the electric current ceases.

1513. "Insulators." A. Gilbert, G. Wells. Dated April 12, 4d. The invention has for its

Fig. 2.

object the production of an insulator so constructed as, without affecting the insulation, to secure the wire, so that, in the event of the wire breaking between any two posts, the other parts of the wire on the other sides of the posts between which the breakage occurs shall remain securely held as before. Fig. 1 represents a section taken through the insulator in line with the wire; fig. 2, a transverse section. The insulator proper is of the ordinary bell shape. The part, c, has embedded in it at the time of making a screw bolt, b, so that when the wire, after being properly strained, is laid in the groove made for its reception in the part, c,

Fig. 3.

the cap, a, of the insulator, which has a corresponding groove, and through the centre of which the bolt, b, passes, is placed thereon, and by means of the nut, e, it brought to bear lightly upon the wire, f, which is thus rightly held between the grooves in the insulator, c, and cap, a. The bolt, b, is made of the shape as shown in fig. 3, so as to allow of the wire being readily placed in or removed from the insulator, and at the same time to bring the pressure of the nut directly over the centre of the cap.

1511. "Telephone switches." John Henry Johnson. (A communication from abroad by Ernest Marx, Frank A. Klemm, and Julius Kayser, of New York.) Dated April 12, 6d. Relates to certain improvements in the construction of telephone switches. It is for objects simplicity and economy in construction and absolute positiveness in operation, and, stationary hanger-post in combination with a vibratory switch lever and flat spring, so arranged in relation to the main line wire bell telephone and transmitter wire and local battery, that the presence of the telephone in position will positively connect the bell with the main line, and upon the local circuit and its removal for use will cut out the bell, close the local battery circuit, and put the telephone and transmitter on the line.

1559. "Electric lamps." Alexander Melville Clarke. (A communication from abroad by Jean Moric Amilcar Edouard Lacroyer, of Paris.) Dated April 14, 6d. Relates to improved arrangement of electric lamps or burners, which is distinguished from all others now in use by its simplicity, yet great lighting

THE TELEGRAPHIC JOURNAL AND ELECTRICAL REVIEW.

Vol. VIII.—No. 188.

ELECTRIC LIGHTING IN THE CITY.

The most extensive trial of the electric light for public purposes yet made will, about the 1st of February next, be inaugurated in the City of London, as the City Commission of Sewers have adopted a report of the Streets Committee recommending that the tenders of the Anglo-American Light Company, of the Electric and Magnetic Company, and of Messrs. Siemens Brothers be accepted. The first company will undertake the lighting of Blackfriars Bridge, Bridge Street, Ludgate Hill, St. Paul's Churchyard, and Cheapside to King Street, by the Heath system, at a cost of £1,125 for 12 months. The second company will light Southwark Bridge, Queen Victoria Street, and Queen Street, by the Jablochkoff system, the cost being £1,250 for 12 months. Lastly, Messrs. Siemens will light London Bridge, Cheapside (from King Street, Mansion House Street, and King William Street), at a cost of £1,320 for the 12 months.

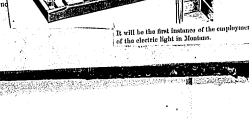
On a rough calculation, taking all the districts together, the cost (including the plant, machinery, fixing and replacing, &c.), will be about four times the price now paid for gas-lighting; but eliminating those expenses, which would not be recurring, the cost would be only twice that of gas, while the amount of light produced will be very much greater.

Messrs. Siemens are the only contractors who propose to bury the conductors wholly underground. There can be little doubt that the latter is the proper course to adopt. Open conductors slung from lamp to lamp, or pass to post, are very unsightly in broad daylight, as any one walking along the Thames Embankment can testify. If any system is permanently employed, underground wires will certainly have to be used, and we think the Commissioners should have insisted upon this course being followed in accepting any of the contracts.

A great deal has been said about the relative values of a large number of small lights compared with a small number of large lights; the coming trial will severely test this question, as the number of electric lights will be very far in excess; thus, number of gas jets they are to displace; thus, assuming in light. According to the tenders, 429 gas lights will be replaced by 116 electric lights, or roughly, 4 electric lights will take the place of 4 gas lights, so that the space between each electric light will be four times that between each gas light. In order, therefore, that the intermediate points between each electric lamp may be illuminated to the same extent as was the case when the gas lamps existed, the intensity of the illumination from each electric lamp will have to be correspondingly increased. It being recollected that the intensity of light diminishes as the square of the distance from the object it illuminates. In other words, if from each electric lamp will require to be four times as great as that given by the gas lamps, are, of course, other considerations to be applied, and which practically modify the above calculation, but the importance of establishing power by space illuminated and not by power cannot be too strongly urged.

During his trip of the Electric Light Arrangements on board the ship was asked to hold an electric lamp which was being swung up to light the stokehold. The man, being ignorant of the danger, grasped the lamp by the brass rod which runs around it, and at the same time inadvertently touched one of the bare wires which supply the electric current. By this act he interposed his body in the track of the powerful current which was, in part at least, diverted from arm to arm across his chest. The shock was sufficient to strike him down dead, all efforts to resuscitate him being unavailing. Nor was the effect due to heart disease induced by the blow, as is sometimes the case with comparatively slight shocks, for it was found next day that the tissues of his body had been disrupted in such a degree by the discharge that incendiate burial was resorted to. There can, therefore, be no doubt that the electric current forcing an ordinarily powerful electric lamp of the Jablochkoff type, such as is used in the Lizzolis, or the other types of Siemens, Lontin, Jamin, etc., is quite capable of causing death to any person who is unfortunate enough to come into contact with it so as to "shunt" the current through any of his vital organs. In passing from one hand to another the current is forced to traverse the breast and lungs, not to speak of the heart and spinal cord. For this reason it is absolutely necessary that great care should be exercised in handling electric lamps, as they are at present constructed. Indeed, it should be made a rule that these apparatus should never be intrusted to any unskilled persons whatever. There is no danger at all about of actual touching with two distinct parts of the body in such a manner as to discharge the current between them; but a person ignorant of the action of the lamp may establish this blunder at any moment, for electricity is invisible, and there is no sign to be seen of the deadly and subtle power which is lurking in the metal stock. Something more than care on the part of those using the electric light would seem, however, to be necessary. There is room for reform in the construction of electric lamps. Hitherto the attention of inventors has been chiefly directed to the proper working of their devices and the luminance of a brilliant light; but henceforth some regard will probably be paid to the safety of their apparatus. Bare wires and terminals ought to be abolished, or at any rate guarded from accidental touch, and electric lanterns made as harmless as ordinary oil-gas lamps were.

[1] The Butte Light in Montana.—A contract has been made with the proprietors of the Brush electric light for one of the largest sized machines, with fourteen lights, with which to illuminate the quartz mills at Walkerville, Montana. These lights will be disposed about the works as follows: seven will be used in the large mill, four in the small one, one in the hoisting works, and two will be placed so as to light the dumps. The illumination afforded by the number of lights will enable the men to work all night as well as by the day time, while the expense will be less than that of ordinary light.



It will be the first instance of the employment of the electric light in Montana.

of the carbons. This was simply done by a pernicious centre screw, like a lying finger post, proclaiming "Go neat this way," tendet to the progress along a good thoroughfare. It only remained to perfect the details of the lamp, to find the best material from which to form the carbon, and so fix this material in the lamp in the best manner. These points, I think, I have now satisfactorily settled, and you see the result in the lamp before me on the table. The carbon in this lamp is a waste body, quite homogeneous and fibrous, fairly in hardness, and becomes harder by the use of the lamp; the longer and the better it is burned the harder it becomes. It is essential to economy in lighting by incandescence that the incandescing carbon should be very thin. The carbon used in two candle lamps and the thickness of the thinnest of the carbons leisurely employed, and therefore, one-seventh of the current, costing one-seventh the price, will produce in this thin carbon the same degree of heat-mobility as twenty times more current in the thick carbons as were used in those ancient lamps."

The great purpose in view, of course, is to obtain a lamp applicable to the lighting of houses, and in view of such application two positives present themselves—one as to distribution, another as to cost. For the distribution of the light Mr. Swan claims to have made ample provision. He puts his lamps in series to, 50, or, perhaps, 100 lamps in one and the same line. As copper wire less than 4th. thick would, it is stated, supply current for one such series of 10 to 100 lamps at a less cubic clearance with a very small percentage of loss. The great difficulty in this system is that a break in any part of the line must extinguish all the lights in the series. To obviate this, it is proposed to use an automatic circuit closer, so that only such lamps go wrong the circuit is still unbroken. On the question of cost, we again quote the author, who says:—

"The economy of lighting by incandescence has not been exemplified by any working instance of actual practical use. One thing is, however, quite clear, and that is that electric lighting by incandescence in an economical process—it will be less costly than gas lighting. That is confidently demonstrated by the fact that 1 per c. of gas employed in working a gas engine to develop an electric current, and used in my lamps, will yield more light than one 6, of gas consumed in the most economical way in gas burners. This room is now lighted by twenty of my electric lamps, and to produce the same light by the consumption of cubic feet of gas per hour are being burnt in a gas engine: before my lamps were finished the room was lighted by seventy gas jets, consuming 5 an hour, and, also 2, per hour. It is very evident that we have got some light out of the gas through the medium of electricity than was got from the larger quantity of gas which those burners consumed. From measurements carefully made, both of light produced and current required to produce it, I am warranted in saying that 1 cubic foot of gas will be produced by 1 certain quantity of gas used to generate an electric current employed in my lamps, and that to obtained from this quantity of gas burnt in gas burners in the usual manner. If that is so, then it is evident that when, instead of the motive power of gas, that of steam produced in the most economical manner is employed, this method of electric lighting is very much less costly than gas lighting."

On the merits of the lamp above described, we refrain for the present from offering any opinion, beyond remarking that, whatever doubts may be entertained by those who, like ourselves, have not had an opportunity of seeing the lamp in use, there is in the scientific gentlemen who have heard this remarkable lecture are convinced Mr. Swan has advanced the electric light well within the economic boundary which has hitherto separated it from competition with gas for household purposes.

Charges for Public Lamps.—Complaint has been made at many of the meetings of the Gas-Light and Coke Company, that the Commercial Gas Company, while making successive reductions in the price of gas to private consumers, has not diminished the charge on account of public lamps in anything like the same proportion. While to private consumers the charge has been reduced 25 per cent, the charge for public lamps has been reduced from £4 12s. to £4 5s. per annum. It has now been explained, on behalf of the Gas Company, that hitherto the public authorities have been favoured in the matter of charge for lighting the street lamps, owing to "a desire to cultivate friendly terms." Now, however, it is not legal to continue this advantage, and, consequently, instead of the public lamps getting the advantage, it is distributed among all consumers. Consequently the charge having now been secured in future reductions, public lamps will share with private consumers in due proportion.

Electric and Magnetic Company Limited.—We hope this venture is not launched too late. Rumours are abroad, that the Telephone has made its appearance once more, and that the Electric Light Company's shares have consequently suffered a heavy depreciation. We have supplied with pure, cautious in the advent of the electric light, and on the unfortunate Company have given special attention to Electric Bells, and Patent Lamps. Under these circumstance should arise likely to impede the success of what promises to be a valuable addition to gas consumers. We shall subjoin to the subject more fully next week.

IRON.

THE JABLOCHKOFF ELECTRIC LIGHT.

THE prospectus has now been issued of the Electric Light Company (Limited), the nominal capital is placed at £500,000 in £10 five per cent. preference shares, ten only of which are to be issued now. The company is to take up the Jablochkoff system of electric lighting, and has entered into an agreement with the Société Générale d'Electricité of Paris, by which it obtains the patent rights relating to the Jablochkoff system in the English colonies and dependencies, except India, as well as those existing in the United Kingdom itself. The works and machinery of the French company here will also pass into the hands of the new undertaking. The payment for these rights, privileges and chattels is to be made solely in fully paid-up ordinary shares. We may add that the company is formed with the object of developing the application of electricity to lighting and other purposes. The report of the Select Committee of the House of Commons on lighting by electricity is referred to, and also to the value of electricity as a source of light. Mr. Edward Graves, F. Inst.Elgrineer and Mr. Keates, to the Metropolitan Board of Works, upon the working of the Jablochkoff system on the Thames Embankment, proves the successful practical application of the electric light to public thoroughfares, and recognises "the superior suitableness of the system." Its use in the many and various establishments in the United Kingdom and on the Continent, where it has been for a considerable period successfully employed, proves its usefulness for general purposes. The contract between the Metropolitan Board of Works and the Société Générale d'Electricité of Paris for lighting the Thames Embankment and Waterloo Bridge, has recently been renewed for 12 months; this contract having been renewed by the Board after more than a year's experience, is a proof that in their opinion, the Jablochkoff is the best system for public thoroughfares. It has been ascertained in working under this contract that, considering the cost of electric light (Jablochkoff) candles at 1s. 6d. per candle and 14s. per horse power per hour, with moderately gas light at 3s. 4d. per 1000 cubic feet, the electric light is cheaper by 25 per cent. or about 25 per cent. on the cost of gas; and if the calculations are based upon London cost of coke, and it is believed that the comparison will be equally favourable in those towns where gas is cheaper, the cost of producing electricity being also cheaper. In manufacturing districts, where motive power is at the door, the comparison will be still more favourable. The extension of the circuits for lighting to long distances has been developed by the Société Générale, who have lighted the Victoria Station and the Metropolitan District Railway from the same source of electricity as the Thames Embankment and Waterloo Bridge. Circuits of over five miles have been in operation; and, in fact, distance is found to present so little difficulty that London might easily be lighted from one great central station. Any required motive power can be produced by the Jablochkoff candle. The size of candle now in use in England has been considered on account of its being the most generally approved and serviceable. The operations of the Electric and Magnetic Company will comprise:—(1) The lighting of streets, railway stations, buildings, theatres, warehouse, mines, shops, &c., by current. (2) The sale and leasing out the necessary plant for producing electric light. (3) The sale of candles, for the manufacture of within the English and colonial patents will be the exclusive right of the Electric and Magnetic Company (Limited). (4) The granting licenses to counties, provinces, towns, and corporations, &c., &c. (5) The supply and application of electricity in any other manner, from all of which the directors look for a considerable and gradually increasing source of profit.

ELECTRICITY AND GAS.

THE following letter by Dr. Siemens has been forwarded to *The Times*, in reply to that of Mr. W. H. Preece, on "Electricity in Galleries," which appeared last week:—

"Mr. W. H. Preece, in addressing you on the subject of 'Electricity in Galleries' on the 28th October, points out very properly that, in his opinion, the employment of the electric light would not be without danger in coal mines, because the electric arc and the incandescing carbon between carbons would be liable to ignite a gaseous explosive compound. When examining the Haswell Colliery, near Durham, on behalf of the Mines, I drew attention to this effect, suggesting only an indirect application of the electric light, by which, if necessitated, the chances of danger might be minimised. I am glad to see that Mr. Preece has come to the same conclusion. The electric light generally and under ordinary circumstances is, however, not dangerous to life and property; his statements to the contrary notwithstanding. I have actually caused unnecessary alarm to three fire brigades, and, incidentally for the illumination of public buildings, by the accidental breaking of a mere crack or pinhole were the arc in an insulating medium, the currents would escape to earth, generating heat and producing fire," emphasising this statement by asserting that it is not a chimerical danger, but the effect of practical information of his own. Now, the electric current is powerful in the sense of doing work, and effect of work, but its intensity is so moderate that it is only of taking the two unprotected conductors against one another that sparks or arcs are produced. The interposition of a thin sheeting of wood or other inflammable substance would in itself supply a sufficient insulating separator to prevent the spark, and I challenge Mr. Preece, notwithstanding his well-known skill as an experimenter, to the production of an ignuous discharge through a mere pinhole in the insulating covering of wire or other of the conductors. In practically arranging electric-lights for public buildings, the precautions are simple, merely suggesting themselves, and the likelihood of danger to building is practically removed by the precautions taken. Mr. Preece's reference to the unfortunate occasion and Russian ballet, may appear to have been struck dead by electric discharges while standing in part of an electric light, is somewhat sensational. They must have been predisposed to succumb to an electric shock, and must have grasped from one the two conductors leading wires with moist hands; for I and many other persons have frequently touched both poles of a powerful dynamo machine without feeling any the worse for it. At the same time there are dangers connected with the establishment of this, as of almost any apparatus or machinery, which do not in any way apply to the gas, but not upon examination danger. Mr. Preece also charges the electric light with being cold in expression, but has the Argand flame the source of heat which science possesses? Now, I quite agree with him in this latter respect, that the electric light is structed as at present made for lighting large spaces, and that it will be left to agent the inference that because the electric arc is cool, electric light must necessarily heat rooms in which it is employed to anything like the same extent as gas, candles, or other illuminants. By the following simple calculation, based upon actual experiment, I will show what is the relative heating effect of the two sources of light within a room. To produce 2000-candle power by electricity there is required of 34 Webers, which again represents 136 heat-units per minute. To produce the same amount of light by gas, 5 cubic feet are required, consuming 16 cubic feet of 10-candle gas per minute, which consumption represents 15,000 heat-units. Some additional heat will be produced in the electric arc, however, by the combustion of the carbon points, but even if this production amounts to 6·3 grains of carbon per minute, and will thus given in London at 1s. per ton. The total amount of heat produced by the electric arc is, therefore, 150+1·5=151·5 heat-units per minute, or rather less than 1 per cent. of the 15,000 heat-units produced by gas. Besides the consuming of the Gas-lights produce, however, the further inconvenience of depleting the oxygen of the air by carbonic acid, and by a minor, but still very sensible amount of sulphurous acid. "If this calculation be set against gas as a heating agent, it proves, on the other hand, its great value as a heating agent; and for one, when so much is said about the smoke nuisance, I may be allowed to add a few words on that subject. The question of the steps to be actively engaged upon the development of a system of working furnaces for the manufacture of iron, steel, glass, &c., by means of gas-fuel produced in a simple gas-gas-making apparatus. Numerous advantages will undoubtedly be found to accrue from the use of gas may be used operation, and furnish daily proof of its value in economical results as the smoky factory chimney, which is now generally considered to be the price where it still exists, proves simply a disregard for the principles of economy. In the year 1853 I was anxious to take steps to introduce the same direction in promoting to supply a better and less wasteful gas, and, having induced the Town Council of Birmingham to support my plans, measures were taken to obtain Parliamentary power to carry them into effect. It was intended to separate the two constituents of coal by a comparatively inexpensive method, supplying gas of low illuminating, but high heating power to consumers at a cheap rate, and reserving the coke for use in locomotive engines and stoves, for which purpose it is well adapted. The Bill was lost—but when, a few months later, the Bill was brought out by a committee of the House of Lords in consequence of the Sanitary Act, including the idea of smoke prevention, and the promoters had consulted me on the subject. While it is admitted by many that gas fuel can be used advantageously for heating furnaces, there still exists a great objection to its use upon the domestic hearth, which is one of the largest sources of consumption of coal, and certainly the cause of a great amount of smoke in our metropolis. The gas fireplace sometimes used does not meet with public favour, owing to its unchecked appearance, great consumption of gas, and most of all, from the evil which frequently results from its use. It is said to produce a 'dry' heat—but when, to my mind, conveys no definite meaning, seeing that the heat produced by an open fire is equally dry, and that, precluding the idea of smoke, there is no heat in the products of combustion of gas, consisting of a number of gas jets spread over a fire-grate, and which is with practice since or asbestos, the heat is not derived from the combustion descend through the grate bars, and thus first their way into the apartment.

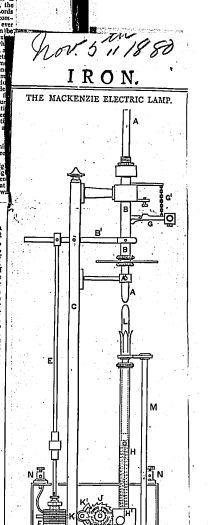
Electric Lighting in 1879.—The Committee of Sewers, on the recommendation of the Streets Committee, were to have been asked on Tuesday last to adopt the tenders of the Anglo-American Electric Light Company (Brush system), the Electric and Magnetic Light Company (Jablochkoff system), and of Messrs. Siemens' Brothers, for lighting the Embankment of the City, at cost for twelve months of £5060; but the matter was adjourned.

Nov. 5th 1880

IRON.

THE MACKENZIE ELECTRIC LAMP.

IN the accompanying engravings we illustrate a recent addition to the gradually increasing list of electric lamps. This is the Mackenzie lamp, which consists of a platform, P, and a standard, C, carrying a lower arm, B, and upper arm, A, each having a holder, H, which holds the upper or positive carbon, A—A, and, E, fixed to the lower carries the keeper of an electro-magnet, F, which, when the current is passing, is held down, and, when it ceases, raises the holder and carbon so as to form the electric arc at which the light is developed. When, from the consumption of the carbons, the current is weakened, the keeper is released, drops the lever and inhaled holder to descend. The small weighted lever and cam, G, being held up in this latter position by, G, allows the carbon to drop on the lower one, L, thus making full contact. when the keeper is again attracted, and pushs the lever and holder up again—the small weighted lever and cam descending, and holding the carbon light. The lower and negative carbon, L, is held in a tube, having a spiral spring, K, which presses the carbon upwards. The spiral spring is held down by a chain, H, which is attached to it, the other end being wound on a barrel to which an escapewheel, J, is fixed. The escape-wheel, J, is held by tooth by the lever, K, and pallets, K, every time the keeper attached to the lever, B, moves to release, is exhausted to burn five hours, and gives the light of 1600 candles, with about four-horse engine power; but it is obvious that it can be constructed to take very long carbons, and, consequently, burn for a very long time. These lamps are being introduced by the manufacturers, Messrs. Steele and Co., of Osnaburgh Street, Regent's Park. Two of them have been in successful operation at the Entrance Hall of the Philosophical Society at Glasgow. The current is supplied by a small dynamo-machine, and each lamp—either Siemens' or Gramme's will suit—requiring about four horse-power to drive it.



SCALE ¼ FULL SIZE.

ELECTRIC LIGHT IMPROVEMENT.—One of the great drawbacks to the economical use of the electric light is the waste of light attending the use of ground glass, no proper substitute for which has been suggested until now. A Frenchman, Mangenin, has been trying recently to use finely ground glass or "glass wool" for diffusing the light of the electric arc, the object being to destroy the wonderful clearness attending the employment of the naked light. By holding his globe, which is cut in shape with a pair of scissors, placed over the arc, the wool, which is closed at the top and bottom, retains the glass dust. The globes are afterwards cleaned by a peculiar process, so as to yield clear glass as much finer than the finest ever made. It is stated that he succeeded in reducing the absorption of light from 16% with ordinary globes to 10% by the use of his improved apparatus.

Death in the Electric Lamp.

It seems as though great improvements in the way of lighting are attended with peril to life, whatever the medium employed. Kerosene numbers its victims by thousands, and the light of the future—electricity—has already caused the loss of two lives abroad by careless handling. In Manchester, England, a person inadvertantly touched the exposed connections and diverted the current through his body. On the Brindisi a similar accident occurred to a sailor who was hanging an electric light in the fire-room. He grasped a brass rod which runs around it and at the same time allowed one of the connecting wires to swing against his body, thus sending the powerful current through it with instantaneous death as the result. With the rapid increase of electric lights in this country, the above record will show that they should not be handled by the inexperienced.

A Modern Electric Light.

A Mowbrie Electric Light, constructed for the Admiralty authorities by the Anglo-American Electric Light Co., was exhibited experimentally on the 21st ult. from the top of the company's works in the York-Town, Lambeth, London, and proved to be one of unusual brilliancy and penetration. This light is produced from a "Brush" machine, and is computed to be of 47,000 candle power, three considerably surpass, the largest and most powerful single light ever produced. The carbon poles used are 11 in. in diameter and to supply this with the current conducting wires 1 inch in diameter are required. The Brush machine employed in generating the current is of the same size as that used for producing 10 lights, but it is so constructed as to give in one light an excess of the total amount of illuminating power developed by the 16 lights, thus illustrating the superior power of Brush's system of dynamo-magneto machines. This machine is driven by an engine of eight-horse power, developing 14-horse power, which is that required for driving. The light, as viewed from the Thames Embankment, Northumberland Avenue, and the Houses of Parliament through the fog which prevailed, presented a very extraordinary appearance, indicative of great power.

The Edison Electric Light.

The Edison Electric Light Company has levied an assessment of $60 per share on its stockholders, and the books have been closed for that purpose to remain so until Dec 1. It is claimed that more money was needed to carry on experiments than was anticipated, and advances were obtained in consequence from some of the larger stockholders until the total sum due now reaches $150,000.

The assessment is for the purpose of paying this, the original capital being $500,000. Certificates of indebtedness will be given to those who pay up, which will be interchangable into new stock when the capital is increased. A meeting with this object in view is to be held shortly.—N. Y. Times, Nov. 6th.

THE ELECTRIC LIGHT—WHAT MR EDISON SAYS.

We printed last week what had been said respecting Mr. Maxim's carbon for the electric light. In a recent visit to Mr. Edison's laboratory there were found burning brightly, and with almost perfect steadiness, a dozen incandescent lamps, furnished with the bamboo carbons shaped like a hair pin. In the machine shops a score or more of men were hard at work preparing the material for an experiment of considerable magnitude and importance that Mr. Edison expects to make in little more than a fortnight. Several of the men were putting in place the parts of an immense dynamo-machine of 1,500 horse-power, with which the attempt will soon be made to operate a great number of lamps through eight miles of wire. It was the original intention of Mr. Edison to test the practicability of operating on this extensive scale in England, but he was disappointed in the Philadelphia machinists to whom he gave the contract to furnish the steam-engine for the dynamo-machine. This machine differs from the machines heretofore used at Menlo Park, and designed to do the work of a large number of them, and therefore better results at half the cost in plant. While draughting-room several men were putting the finishing touches upon their specifications for an elaborate system of electric lighting, including the plans for a number of central stations to be built in the city of New York. Mr. Edison has also built a factory for making carbons, and has taught a number of boys how to blow glass. As to the factory it is the expectation to have lamps made for use in New York when the company begins to enter the field against gas. have been finally and satisfactorily made. Vacuum pumps have also been perfected to prepare the lamps for use.

Reference having been made to what is claimed for an incandescent lamp under the Maxim's patent, Mr. Edison said that he had read what had been published on the subject, and that the claims for it were unfounded, for instance, the claim that it is the first lamp to utilize the portions of a divided electric current. "Every person," says Mr. Edison, "familiar with the history of the art of electric lighting knows that I was the first person to divide the current and use the portions. That was by the lamps I exhibited here last winter." "There is nothing new," he added, "in the principle of electric lighting by incandescence, lamps on that principle were made thirty years ago. The novelty is in establishing the current and utilizing the divided portions, thus producing many lights of less brilliancy; and this principle of subdivision is my discovery. I could have done six months ago what Mr. Maxim has done, but I decided to make a show. I did put my lights in the steamer Columbia in May last, and they have been in use ever since."

When asked if the Maxim lamp infringed upon his (Mr. Edison's) patents, Mr. Edison replied: "Maxim has infringed three of my patents and thirteen specifications. One of the men peculiarly interested in his lamp has admitted that it is nothing more than my lamp slightly modified. No doubt the display made by Maxim has a distinct object in view. I have been urged to operate my lamp in New York and have declined, because there is no object to be gained. There is no stock to be sold and I am not in the show business."

In answer to a question whether he had not been experimenting with bamboo carbons, expecting trees there great results, Mr. Edison said: "I have been testing a great variety of carbons. There is nothing in the bamboo to entitle it to superior consideration, except that it is very uniform in texture and has fewer imperfections than any material yet tried. The carbon of bamboo itself has no especial property to recommend it."

It is understood that an agent of Mr. Edison's company is to explore in Brazil, for which country he is about starting, for special growths in palm wood, of which there are many varieties in that country, with a view of finding the exact growth of fibre that fits the required use in lamps for lighting by electricity.

"I have been working," said Mr. Edison, "with a view of obtaining a steady light of about 16-candle power. The public may be taken at first with a light of great brilliancy, but people would soon become tired of such light in their houses; it would pain the eye and make it weary. In fact, people would soon get sick of such a light and have it removed. A moderately bright light of perfect steadiness is what is wanted."

"In a word, then, your object is to reach the point of successful competition with gas, and you are hopeful of reaching that point?"

"My object is to devise the means of establishing electric lighting on a commercial basis; to distribute the current from a central station and measure it, as gas now is, and to bring the cost down to a point where the enormous consumed influence of gas can be successfully encountered. I have no doubt whatever of success. The plans and specifications for central stations for the City of New York have been made, and proposals have been received. There remains nothing except for the company to obtain the permission from the authorities of New York. If that is done I expect to lay wires in January."

Mr. Edison also said that several persons in Geneva had become interested in this light, and that capitalists of that city had formed a company and went here to Menlo Park to learn the business. These men are now working daily in the laboratory and shops of Mr. Edison. The Swiss were greatly attracted by the brilliancy of the lights. One of the Edison lamps was run up to 2,500 candles at Geneva.

THE ELECTRIC LIGHT ON WESTERN RIVER STEAMERS.

From present indications the electric light is destined to play an important part in inland navigation, particularly on the immense rivers of the West and Northwest. As a rule the Western river men are very slow to adopt new ideas in the line of improvement, and the safety guards in the pilot-houses of their steamers are a case in point. Before they can be induced to believe that the electric light is a success they must be satisfied that it will not dazzle the eyes of the pilots, for slight annoyance of this character at the steering wheel would be fatal to the safety of the steamer and all on board of her.

Electric Light in Belgium.—A new electric lamp has been brought out at Brussels by MM. Clerk and Herson, engineers. It consists of a piece of marble or granite with holes in it, through which the wires fall through, the arc account of the shape of the holes, all burning, the being formed between the points which come through the grains. It is said to be more economical than Jablochkoff light gave equal to 100 Carcel burners as against 40 for the Jablochkoff candle. It takes about two horse-power to feed the lamp equal to 100 Carcel burners, and the lamp will burn for twenty hours without any adjustment.

The Lorin Light.—The Eastern of France Railway Station is now lighted by the system of electric lighting, which, after trial in the goods station, has also been adopted in the passenger station of the Lyons and Mediterranean Company.

DECEMBER 11, 1880.

Light has been affixed to some of the finest steamers on the Mississippi and Ohio.

The first boat to adopt the light was the Reuben R. Springer, plying between Cincinnati and New Orleans, and to-day the list includes the S. H. Pratter, the Mosher, the C. P. Choutesu, and Golden Crown, on the Mississippi; the Scotia, on the Ohio; and the new steamer Iron Age and Iron Duke, plying between Pittsburg and St. Louis; also the towboat Harry Brown, described some time since in these columns, and engaged in coal towing between Pittsburg and New Orleans. Other steamers will shortly be fitted with the new light. In most cases a single light is used, of 1,600 or 2,000 candle power, and located at the forward roof of the cabin deck. The carbons are placed in a movable lamp, similar to a locomotive "headlight," whose reflector projects the rays to the point desired, keeping the pilot house and the rest of the boat in shadow. To drive the generator an independent engine, vertical type, 8 or 10 horse power, is located in the engine room, usually 200 feet or more from the lamp. The main result so far is noted in the reduction of the time required in making landings. With the old cresset or "torch" the pilot was unable to land at the precise point desired, and backing and reloading was necessary. But with the electric light every object on shore is clearly defined in the darkest night, and the boat touches the shore just where desired. The handling of freight is also facilitated greatly. In coal mining, the Western pilot as yet refuses to tolerate the light, and prefers the old time guides of hills and other landmarks. In fog also the electric light is pronounced useless. When steamers are fitted with two lights, the second is portable, and can be taken on shore or moved portion of the boat, as may be necessary. or of the "tow" of coal craft surrounding the steamer. In all these cases the Brush light is used.

Mr. Swan's Electric Light.—Mr. Swan will bring his new lamp before the Society of Telegraph Engineers on next date—probably December 8.

The Gower-Bell Telephone.—We understand that Her Majesty's Government have presented the Sultan of Morocco with a pair of the Gower-Bell Company's long-speaking telephones.

Chatham.—The dockyard is to be lighted by means of the electric light, and if all goes well, one of the three projects will be tried and the most successful, in all probability, will determine the one best adapted for the purpose in view.

On Wednesday, November 17th, the quarterly meeting of the Society of Telegraph Engineers was held at the Institution of Civil Engineers, Great George Street, Westminster, S.W. The business, a Dr. Siemens in the chair. There was a large gathering, to receive the members, of the Society of Electricians. This latter is the junior of the two societies, and the society exists, it would appear, for the purpose of reading papers which cannot be read before the senior. Dr. Siemens, in a few words, explained the objects of the Society of Electricians; and C. E. Spagnoletti, Mr. Newton's successor, read a paper on the making of the Brush electric light machine.

Maxim's New Electric Lamp.—Mr. Hiram S. Maxim, of New York, has devised a new focusing electric lamp for use in connection with the telephone or any similar purpose of his design which we described in a recent issue. One great quality of the lamp is the sturdiness of its make; quality of the lamp is the sturdiness of its make; but there is no very great feature in its mode of action. As in the Dubosq, Serrin, and other forms before us, the carbons are simple vertical rods, the top one having a small suppressor. It is carried sensitive one hung loosely by its own weight and by a pillar which descends by its own weight and then feels the carbon that is consumed to the arc. In addition to the pillar actuates a pair of toothed wheels descending pillar actuates a pair of toothed wheels descending by grades of a screw, and the top one carried it is carried by a screw and nut. This is driven by a small electro-magnet through wheel and pinion gearing. The negative which the feed current is supplied to the lamp. The carbon is also fitted with a short holder which carries a pulley at its lower end. This pulley rests, as usual, on the top of the positive carbon holder, and by means of the feed wheels is lowered to a certain extent, holder can be raised or lowered to a certain extent, so that the negative carbon as well as the positive carbon is adjusted automatically by the current. The lamp is started by allowing the negative one, when to descend into contact with the positive one, when the current immediately passes, and by enabling the electro-magnet locks the train of wheels and stops the descent of the upper carbon, at the same time it lowers the pulley and allows the lower carbon to recede from the upper one; thus establishing the arc. As the positive carbon is consumed the arc widens, and the current weakens till the force of the electro-magnet is unable longer to detain the wheelwork. The positive carbon therefore resumes its descent until again stopped by the increasing strength of current in the longest proving sufficient to lock the gear.

Engineer, March 18, 1881

THE TRIAL OF ELECTRIC LIGHT APPARATUS AT GLASGOW.

WHEN last week we described the work at Glasgow connected with the trials of electric light apparatus, we certainly laboured under the impression that we should at length obtain real and tangible evidence as to the comparative value of the rival systems at present before the public. Unfortunately, however, only one maker could be found who would submit his lamp to the tender mercies of the jurors or the dynamometer, but, as far as is, nothing is known, except that machines under trial were then made according to the system of Gramme; whilst of lamps that of Mr. Crompton has been thoroughly tested, that of Brush being, after much vacillation, withdrawn. It is a sad pity that exhibitors should be allowed to withdraw. The withdrawal may be, say frequently is, prejudicial to the interests of the public, but it is also unfair to judges, who have to spend much time and energy in order to bring exhibitors to perfection. Of course the very facts the public desire to know are those which vendors of electric light apparatus desire should remain unknown. Which lamp gives the best light with the least cost? The trials at Glasgow would have definitely settled the value of all lamps entered for competition, but, as it is, nothing is known, except that Mr. Crompton has an exceedingly good lamp; and that a slight variation in the internal resistance of a dynamo machine has an appreciable effect upon its efficiency. In the main this information is not new, but the jurors' report will contain figures giving exact instead of general information. The three Gramme machines, by three different builders, tested, differed slightly in make, although, perhaps, not more so than any three tenders by the same maker. The first of (1) Jurgensen had a resistance Brush to brush = 0·750 ohms, from terminal to terminal of 1·097 ohms; that of (2) Sautter Lemonier had three resistances respectively 0·745 ohms and 1·098 ohms; and that of (3) Nilgren Hemmingway 0·616 ohms and 1·07 ohms. The Gramme machines ran at (1) a resistance of 1·098 ohms with 0·93 webers, and (2) a resistance of 1·098 ohms with 903 revolutions per minute; (3) 2·10 ohms power to produce 32 webers through a resistance of 1·07 ohms, with 1,134 revolutions. The values of (3) we have not yet received, a belt bearing preventing the taking of frictional diagrams. Nor have we the exact results of the photometrical measurements made with the Crompton lamp, but from other experiments made at Glasgow, though not for the jurors, we have every reason to believe that those measurements will assist in showing that it is, if not the best, one of the best lamps in existence. We must again revert to the misfortune of there being no public, unbiassed, and exhaustive testing of various machines and lamps, and trust that should any further exhibition of electric light apparatus be inaugurated, a condition of the exhibition shall be that the whole be tested in competition by men who thoroughly understand the subject. The jurors at Glasgow were of the greatest ability, and the testing would, if carried out on a large scale, have given us trustworthy information of a valuable kind.

Engineer, March 25, 1881

MECHANICAL TRIALS AT GLASGOW.

FOLLOWING up the brief general article which appeared in our issue of last week on the subject of the electric light trials in connexion with the Exhibition of Lighting Appliances at Glasgow, we now proceed to give some notes respecting the testings referred to. As mentioned in our former article, the trials that had then been instituted were confined to the dynamos and other apparatus shown by Messrs. Crompton and Co. These exhibits included (1) an A Gramme machine, made by Messrs. Jurgensen, Sautter, Lemonier, and Co., of Paris; and (2) another Gramme, of the same pattern, but made by Messrs. Sautter, Lemonier, and Co., of Paris; and there were also Mr. Crompton's lamps in their most improved form, and an engine constructed by Messrs. Marshall, Sons, and Co., of Gainsborough, by which the above named machines were driven. The engine is fitted with Hartnell's automatic expansion gear, which was found to act admirably, the distribution of the steam, as shown by the numerous indicator diagrams taken, being excellent.

The aim of the Committee of Jurors was to test the engine most thoroughly as to the power developed, then to trace that power into and through the dynamo-electric machines, and lastly by means of a photometer to determine the amount of illuminating force cut by each lamp. As carried out on the night of the 25th ult., the experiments were conducted on the principle of the division of labour, two or more of the jurors and assistants being engaged at each stage of the work. Starting at the engine, the power developed by the engines was determined by indicator diagrams, a method that, absurdly by the machines was measured by a dynamometer which was taken down to Glasgow by Dr. John Hopkinson, F.R.S., who had been specially engaged by the Executive Committee of the Exhibition to assist in carrying out the important experimental inquiry placed at by the Committee. The dynamometer used was that designed by Herr Hefner von Alteneck, and it was described by Dr. Hopkinson in a paper read by him last year before the Institution of Mechanical Engineers. The indicators used were most carefully tested and compared, and, as far as was possible, every means were taken to insure accurate results.

If we now turn to the consideration of the power used by the dynamo-electric machine which was first tested, we find that the mean gross horse power was 2.51. The frictional diagrams of the engine and dynamometer gave 2.92 horse power, and after deducting that amount we get 2.19 as the horse power used by the machine in producing a mean current of 32.5 webers, through a resistance of 1.098 ohms, exclusive of the arc.

In regard to the second machine tested, that made by Sautter, Lemonier, and Co., it should be mentioned that owing to the position which is occupied on the tumbril, the dynamometer caused the belts to be far too tight, thereby causing a slipping of the machine to become very considerably heated. The diagrams taken under these circumstances show that the horse power gradually increases in consequence, and it would scarcely be fair to judge of the efficiency of the machine under such conditions. The mean gross horse power taken at this stage was 7.06, and deducting 2.92 horse power, as before, we get 4.14 horse power used by the machine in giving a current of 31.19 webers.

When the third machine was under test it showed a mean gross horse power of 6.57, and after deducting 2.92 horse power, as in the other two cases, we have 3.40 horse power used in producing a current of 29.2 webers through a resistance, exclusive of arc, of 1.447 ohms.

Some diagrams taken by Mr. Crompton, also, when all the three lights were on at once show a gross horse power of 11.6. If only 1.6 be deducted as the engine friction we have 10 horse power for each light, which corroborates the general results obtained from the other diagrams.

The current passing through the light was measured by one of Siemens' electro-dynamometers. In this instrument, which is an application of one of Ampere's experiments, a copper frame, round three sides of which the current to be measured is led, is suspended by a silk thread, and the compensations to it are made by the extremities resting in cups filled with mercury. Four coils of brass the current next passes through an insulated wire forming several convolutions round the suspended frame. The tendency of the frame to be rotated by the current is opposed by a spiral spring, which, again, is supported by a moving head carrying a pointer revolving above a divided dial. When the current is passed through the dynamometer the frame is deflected, and it has now to be brought back to zero by the adjustment of the spring already mentioned. The number of degrees through which the head of this spring requires to be turned in order to effect this is read, and has now to be brought back to zero on a table worked out for each instrument.

Mr. Crompton's lamps, of the E pattern, was the one that was tested. In it the magnet coils are formed of wire of No. 11 B.W.G., surrounded by a secondary shunt coil of fine wire having a resistance of 120 ohms. The carbons used were made by Messrs. Sautter, Lemonier, and Co., and were 13 mm. in diameter.

It was finally arranged that the photometric experiments should have been carried out as follows: Two seats on the Corporation Gasworks were to be taken, one of direct light, the measurement, and another taken at an angle of 45° on the horizontal line. In the latter case the light was to be received on a white screen, and the measurements were to be made by a Bunsen photometer. The experiments were to be carried out as follows: The engine was to be started, and the dynamometer and indicators applied. The engine was to run a sufficient length of time to enable the dynamometer to get warm, and then the indicator diagrams were to be taken. The engine was then to be stopped, and the dynamometer and indicators removed. The engine was then to be started, and the lamps lighted, the current being carefully regulated by the electro-dynamometer

Miscellaneous News

ELECTRICITY.

SALT LAKE CITY, Utah, Nov. 13.—Ogden, Utah, is the first city west of the Mississippi River to adopt the electric light. A flag-staff sixty feet high is to be surmounted by a three-globe arc lamp, giving an elevation of 200 feet, from which will be distributed 10,000 candle power each arc, sufficient to brilliantly illuminate a space one mile in diameter. The lights are to be in operation before the first of February.

The annual report of the Lighthouse Board for the last fiscal year says: "It will probably contain an interesting review of the progress which has been made by the electric light during the year. In order to give the electric light a proper test, the Lighthouse Board, if further encouraged by an appropriation of $50,000, is recommended to place one of the new lights in the system of lighthouses, stationed on the Atlantic coast. Additional appropriations will be asked for to finish the lighthouse in the Detroit River, and for the testing of a system of constructing new lighthouses will be submitted exclusively with Congress.

It seems as though great improvements in the way of lighting are attracted with zeal to life, whatever the medium employed. Kerosene, petroleum, gas, Drummonds, and the light of the future—electricity—has already caused the loss of two lives formed by the explosion of a gas-chandelier, England, a paper journal-ist testily remarks, exposed connections and diverted the current through his body. In the London shelter no such casualties occurred to a visitor on his lamping an electric light in the fire-room. He found the wires in a safe position and at the same time allowed none of the connecting wires to swing against him lastly, that the electric current through his body was only 1-20th of a milliampere, as the meter registered. Though it will fascinate lights in the country. With the rapid increase of electric light people can be furnished by the inexperienced.

In the Glasgow exhibition of electric and gas lighting apparatus is a complete, portable, self-contained gas-engine, of large lighting capacity, of 10,000-candle, capable of lighting thoroughfare, hall or railway station. Its weight is 4 tons. It consists of a 6-horse power Otto silent gas-engine, by Messrs. Crossley and Co., by Messrs. Otto's steam engine, made for the purpose by Messrs. Crossley Brothers, and by Messrs. Crompton, which is mounted with the engine upon a strong framework, by which they are borne by the driving-wheels. The dynamo-electric machine, by Messrs. Crompton, has two or more sets of coils and field-magnets, driving the rather peculiar form of driving two belts, one outside the other, to suit a width of 8 inches is necessary.

Dr. Siemens has written a long letter to *The Times*, in reply to Mr. Preece's communications on the subject of the danger of the electric light, to which we alluded last week. We are not concerned with the differences on electrical matters existing between these two eminent authorities; but Dr. Siemens comes more within our province when he goes on to speak of the value of gas as a heating agent, with direct reference to the present agitation on the great smoke and fog question. Dr. Siemens points out that in the case of factory furnaces, which are responsible for nearly the consumption of fuel to such a measure as to cast forth smoke from the chimneys, by the more modern use of gas firing all smoke is not only prevented, but a considerable saving effected. The veteran originator of the regenerative furnace goes on to advocate the use of gas fires upon the Thameside hearth, out of the usual pattern, which may be procured perma- ently and economically. Considering probably for the first time Asbestos kept in an incombustible state by a gas-flame known beneath, but in a combination of coke and gas with a solid plate substituted for a fire-grate. The gas is supplied at any pressure from the front, and Dr. Siemens expresses himself in the highest satisfied with this arrangement, which he made in his own house. The combination is not new, having been introduced nearly thirty years ago, somewhere about the time when Dr. Siemens says he tried to get a Bill through Parliament for supplying Birmingham with heating gas, in which he failed, as he states, in consequence of the opposition offered by the local Gas Companies. We do not here wish to take up the subject of a controversy which terminated so long ago, especially as there is no apparent intention on Dr. Siemens's part to renew it. It may, however, be said that the failure of Dr. Siemens's efforts at that time was due to other causes than the opposition of any local competitors, although they may have had the attack on the invention. We must regard the project of supplying a heating gas in the summer proposed as having failed in reality from its own weakness, or it would assuredly have been adopted elsewhere, though Birmingham would have none of it. In such cases as this, where two analogous processes contend for mastery, and one is victorious while the other becomes extinct in consequence of one obtaining more or no doubt that it is the fitter which survives. Dr. Siemens, of course, could scarcely be expected to put forward these considerations, and, after all, the chief interest of his letter is to be found in the statement that he has discovered a satisfactory means of using common coal gas for the purpose of warming his residence.

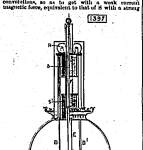
Engineering, speaking of the lighting of the Royal Albert dock, by Siemens lamps, says it is "the most extensive installation in the world of the electric light." The space, 8,500 feet long, and 200 feet wide, is lighted by 27 of Siemens pendulum lamps, placed on iron poles 80 feet high, the "electric illuminants" are of each lamp being equal to 2,000 ordinary gas-burners." The electric light is slightly cheaper where the arc, and not with them the leading for 4 engage, it stops

A SECRET item of the *Glasgow Herald* contains a account of the experimental application of the electric light at the Govan Graving Dock at the Glasgow Exhibition, under the direction of Capt. Douglas, R.N., C.B., Admiralty Superintendent of Dockyards, and Mr. Robert Hunter, engineer-in-chief of the Clyde Navigation Trust. The dock is the largest in the kingdom, which is to be permanently lighted by it.

wicks. To relieve the speed controls the pendu- l is lowered by a counterpoise, which is the cause of a slower movement of the clock-work.

1707. STEPHEN LIGHT, &c., C. *Jet-Action Bath* 5th April, 1880.—Not proceeded with.

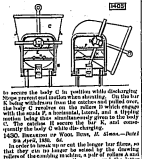
A Gentle sweat says F is free to move within the cylinder, and is fitted with a valve, G, which opens on the ascending motion, and closes on the descent, so that the water, and by in a short stroke of the valve in many convolutions, so as to get with a weak current of magnetic force, equivalent to that of a with a strong



current, and to present considerable resistance. When the armature is at rest, the spring, E, draws the valve, F, away downward with that of D is disturbed, the force F is attracted towards ascending the cylinder. When, on the other hand, the armature is drawn to the magnet, the valve, F, is closed, and the water forced through the valve, G, and escapes through the orifices to the bath. The action of the spring, E, may be varied by the screw, H, which is provided with a milled head, and a scale is applied to the socket tube of the upper screw.

1655. T. THOMAS, C. E. Cooper, *Sand* 4th April, 1880.—Not proceeded with.

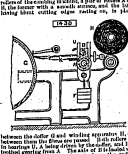
2,000. Thomas, In the end standards, C the body of the trunk, D rollers in parts, and E the end standards of the body. E runs here on which D roll, F sticks in the ground to keep the body from moving sideways. G runs on it. Above are shown on the standards H, I, and with them the looking for K engage, it stops



to secure the body C in position while discharging. Stops pressed and inclines when shown, On the bar E, being withdrawn from the catches as implied over. The bar E is drawn back by the lever L, which is fitted with the ends of the standards, hinged, and a working motion being thus simultaneously given to the body C. The standards are fitted with the ends of the body, and the ends of the bar E.

2,000. Thomas, Improvements in Wool Burrs, &c. *Sheets—Dated* 5th April, 1880.

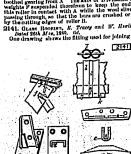
In order to break up or cut the burrs or other foreign matter in wool, the inventor employs a pair of "spiked" rollers, A and B, which are driven at different speeds, A being the faster, and B the slower with a smooth surface, and the latter having blunt cutting teeth, or projections, b, placed



between the flutes of and winding operation H, and between the flutes are passed [illegible] with rollers out in bearings D, A being driven by the other, and it by bevelled gearing from the shaft, E. The wool passing between the rollers is drawn from the ends of this roller in contact with a while the wool about is passing through, that the burrs are crushed or cut by the cutting edges of each.

2,014. Bell, *Sheep and W. Hardie*—Dated 10th April, 1880.

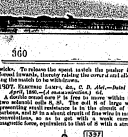
One drawing shows the filling used for joining the



ends of rubber in the slips true and well while respectively, the angle of the tip right part to the base being made to suit the angles which the rubber makes with the edge true and well plate respectively. Another drawing shows the method of joining the ends of rubber which have been previously prepared as above, and are prepared to cause different lengths of the filling for a cost of greater curvature. It is [illegible] that the ends of the rubber are cut to the angle of the tip, and the ends are then placed together, as before A B, joined together [illegible] and formed with dots and dashes, as shown, and the joint [illegible] by the

2193. Sellers Mills and Thatcher Wheat, *Mowers—Dated* 27th April, 1880.—Not proceeded with.

The inventors of a certain so that their guiders can conveniently, and over the [illegible] of the surface of the rollers at 4 and 5 45, the surface of the lower roller is provided with a series of projections, which are [illegible] by the [illegible] of the [illegible] They are driven by belt from a pulley on the roller



shaft e, which is geared with roller shaft a1, and also with the roller shaft b1, by means of the pinions f and f1, and worm i, and worm wheel on the roller shaft b1. The roller shaft a1 is mounted in bearings in the frame, and the roller shaft b1 in bearings in the [illegible] lever l, and regulating slide, and lasting rollers a1 and b1 are fitted with [illegible] and [illegible] against the rubber a at by spiral springs and set screws.

THE PREVENTION OF FRAUDS.—The Leicester Corporation are about engaging an officer to carefully test flood works at a cost of over £30,000, and the Corporation are also about appointing Mr. Mr. Hackesley, for the widening and deepening of the river Soar, at an additional cost of £60,000. It is claimed for the scheme that it will not only prevent floods, but will be a benefit to the town, but will increase the value of property in the neighbourhood beyond the actual cost.

SOUTH LEICESTER MOSSLY.—Visiting-day for the week ending Oct. 30th, was Monday, Tuesday, and Saturday, five, from 10 a.m. to 4 p.m. Number of visitors, 1,555; number of buildings visited, 7; total value of goods carried, £1,000. Thursday and Friday, admission 6d. from 10 a.m. to 4 p.m. Number, 1,555; mercantile marine, building materials, and other articles, £1,000. Total, 2,555. Average of corresponding week in former years, 1,127. Total from the opening of the Exhibition, 13,191.

THE BASIC PROCESS.—A correspondent who has recently visited the principal Bessemer districts and commercial affairs, states that Mr. Thomas, Professor at the Liverpool College, who has been making investigations in regard to the basic process, has come to the conclusion that the Professor's theories will be dealt with the cost of £1,000 per week. In Belgium the process is in full swing, and in Germany it is receiving with that under the Bessemer process. He proves that infinitely of phosphorus in the system at less than 70/. whilst labouring from 1 to 7 per cent. of phosphorus. It is found for the purpose of [illegible], that the material [illegible] have been economical, and that [illegible] by the use of [illegible] is equal to that of a Bessemer retort, and comes to the following table of values:—

Electricity in Collieries.

Mr. W. H. Preece, President of the Society of Telegraphic Engineers, has addressed the following important letter to the *Times* on this subject :—

Sir,—Several correspondents recently advocated in the *Times* the employment of electricity for illumination in collieries. One suggests that portable lamps made of a battery and a vacuum tube should be employed. Such lamps have been tried frequently, but they have failed from want of permanence in the current and intensity in the light. I have seen excellent lamps of this form, notably one made by Ducgnet, of Paris; but they proved much too feeble in illuminating power and penalties. Others propose the use of the electric light on the assumption that such a light is safe.

It cannot be too strongly insisted that the absolute safety of the electric light is a popular delusion. In the first place, the arc itself is the greatest source of heat which science possesses, and, in the second place, the wires conveying the electric currents that produce the arc may themselves be conveying energy in a form as insecure as a train of gunpowder. The degree of the electric arc is supposed to be removed by its insertion *in vacuo* in hermetically sealed glass bulbs; but what if these bulbs be broken, and what about the difficulty in maintaining the vacuum? Granting, however, that it be practicable to immure the light in a secure transparent vessel, what about the wires?

The currents employed to generate the light are extremely powerful, in some cases many thousand times stronger than those employed to work telegraphs. Not long ago a poor musician in a theatre in Birmingham, and quite recently a poor Russian sailor on board the "Livadia," were killed by incautiously seizing upon certain exposed parts of the conductors conveying these currents.

The difficulty in maintaining currents in their proper path in telegraphy is very considerable. How much more difficult must it be to maintain those employed for electric lighting! Copper wires are usually insulated in india-rubber or gutta-percha coatings, but these insulating coatings are liable to injury; they are inflammable, and if a mere crack or pin-hole were to occur in such a coating the currents would escape to earth, generating heat and producing fire.

This view is not chimerical. Offices have been set on fire even by the currents employed in telegraphy. I know of two such cases, one in New York and the other in Boston. It is not at all unlikely that the recent fire in Manchester arose from such a cause. The liability to such accidents is evidently much greater with electric lighting, and it is only technical knowledge and professional skill which can render such currents innocuous even in well constructed buildings. In mines, however, the difficulty is much greater. There the wires must necessarily be suspended in narrow, frequented galleries close to the damp earth, and be liable to incessant injury, and they could be rendered comparatively safe only by costly casings. It would be impossible to guarantee absolute security. To fight a colliery by electricity would therefore be both costly and dangerous.

The popular delusion as to the safety of the electric light is probably due to its being so frequently spoken of as a cold light, the word "cold" being used in its figurative sense of cheerless, the unscientific taking the word in its literal sense.

There is reason to believe that electricity plays another important part in colliery accidents. Some months ago there was a terrible disaster in the Risca colliery in South Wales; over 70 human beings were hurled into eternity. An inquiry was held into the cause of the disaster, and the conclusion arrived at was by unanimous consent that telegraphic engineer, Mr. Arthur Hodgkins, from evidence collected on the spot, arrived at the conclusion that the mine was discharged by a flash of lightning. He submitted his evidence to me, and I fully concurred with him. All the conditions for such a catastrophe were present. The flash of lightning was seen to strike the head-gear of the shaft immediately before the explosion. This machinery was connected with the bottom of the shaft by several continuous conducting masses. Iron rails, resting on poorly conducting matter, extending thence throughout the galleries. The gas was there, and it only wanted a break of continuity in the metallic masses conveying electricity, of which there were many, to produce sufficient heat to fire the charge.

I have no doubt that lightning was the cause of the explosion. These facts were submitted to those who were concerned in the inquiry; but probability, being incomprehensible to them, they were ridiculed and therefore ignored. Hence I advocate the employment of well constructed *lightning conductors* over the *head gear of shafts to keep electricity out of the colliery* and to insure safety, rather than the erection of conductors along the galleries to convey it in from the purposes of illumination and to incur danger.—London *Iron*.

DENORMANN INSULATOR BRACKET.

A most ingenious and practically successful insulator bracket has just been invented by Baron Denormann, the Mediterranean Extension Telegraph Company's manager in Corfu, well known in the engineering world for his numerous improvements in machinery, &c.

The object and obvious advantage of this bracket will be at once seen on reference to the enclosed sketch

Besides supporting the insulator more firmly than any existing bracket it prevents the wire from falling to the ground when it may have slipped from the insulator, broken or split by the thunderbolt and one causes which do break insulators; and by casting the iron with some insulating varnish the wire on alighting would in wet weather show a comparatively high insulation, and enable the line to be worked when, in the ordinary course of events, continuity would be extremely difficult or altogether impossible through the line being to earth.

Another advantage, and a very important one for those countries where poles and insulators are so frequently destroyed by electrical discharges, is the lightning guard arrangement formed by the outer arm of the bracket itself, which is considerably higher than the insulator, and effectually brought into communication with the earth by a wire twisted with the bracket into the pole, wound round it, and conducted down to the soil. In this manner all parts of the world and havoc is made amongst poles and many parts of the world are made amongst poles and insulators during heavy thunderstorms, and undoubtedly the insulators during heavy thunderstorms, and undoubtedly the Denormann bracket should offer great advantage over the primitive lightning protector at present in use.

BRITISH ASSOCIATION.

PRELIMINARY REPORT OF THE COMMITTEE, consisting of Professor W. F. Ayrton (secretary), Dr. C. R. Alder Lodge, Mr. J. N. H. Gordon, and Mr. J. Perry, appointed for the purpose of accurately measuring the specific inductive capacity of a good Sprengel vacuum, and the specific resistance of gases at different pressures.

In 1878 two of the members of your present committee concluded from a number of experiments on the analogy between the viscous yielding of bodies to mechanical stress, and the absorption of the electric charge in a Leyden jar, that some connection of an inverse order would be found to exist between the specific inductive capacities, and the specific resistances of dielectrics. As at that time it was only for guttа percha and india-rubber that the specific resistance was known, it was necessary, in order to put the theory to the test of experiment, to carefully measure the specific inductive capacities of other dielectrics, if which the specific resistances were known. This was done for shellac, sulphur, and resin, and it was found that in general when the bodies were arranged in increasing order of specific inductive capacity, they would be found arranged in decreasing order of specific resistance.

Professor Clerk Maxwell, in a different method of calculation for light, again, since different gases had different indices of refraction for light, it was felt that Faraday's not having succeeded in finding experimentally it was felt that Faraday's not having succeeded in finding experimentally any relation between the specific inductive capacities for the various gases must have arisen from the specific inductive capacities of his apparatus, and very delicate experiments undertaken by the present committee showed that this was the case. Thus, for example, the specific inductive capacity of air, and other gases, is slightly greater than unity, but the specific inductive capacity of glass, ebonite, and gas, sulphuric dioxide, &c., is considerably greater than unity. Hence the resistance of a gas to discharge, or discharge varied with the nature of the material of the apparatus. In addition to the results of Faraday's researches in which the specific resistance of gases was measured by experiments, that the specific resistance of gases was measured by experiments, that the specific resistance of gases is slightly different from unity, a conclusion also ordinary air-pump, it was slightly different from unity, a conclusion also subsequently verified by experiment.

Your committee was therefore reappointed, and has carried out the experiments undertaken for that investigation, which was conducted at Japan, Clifton, by using two insulated concentric cylinders as a condenser, the specific capacity, the other a closed conductor in which the gas at the pressure could be put. The specific capacity was first measured when the air was at the highest pressure which the latter was filled with air at the highest pressure which the apparatus could bear, and then the pressure was gradually reduced, and the specific capacity measured at each pressure. The specific capacity of the air at the highest pressure was taken as unity, and the specific capacity of the air at the highest pressure was taken as unity, and the specific capacity of the air at the highest pressure was taken as unity, and the

Nov 15th 1880

condition relatively to T, so that when the condensers on the two sides of the balance have perfectly equal capacity no sound is heard in an ordinary daily delicate telephone, T, when the commutator are made as in the figure. It will be observed that the effect of the arrangement is to make the influence of insulation in A would make it appear as if there was a less degree of insulation in B, and would be in this case with the method of experimenting previously described.

2. The air at pressures greater than one millimetre the committee have not thought it necessary to make many experiments, but between 0·05 and 0·001 of a millimetre pressure several sets of experiments have been carried out. At the latter pressure—that is, at about one millionth part of an atmosphere—the specific inductive capacity of glass, ebonite, and sulphur is practically identical with that in air, namely, 0·0 per cent., less than that numerically, whereas the greatest discrepancies before the air was thus thrown in the two previous investigations, when the pressure was not reduced to lower than five millimetres, was only 0·1 per cent. At this rate the rate of experiments for very low pressures there are decided waves in the reacting capacity and pressure, but whether these waves are really caused by a physical law, or whether they are due to the method of experimenting still requires further investigation. The committee think that they are due to the capacity not depending only on the pressure, but also on the rate of exhaustion, and that, probably, the aluminium cylinders, the committee have not yet ascertained, and, therefore, in this preliminary report they refrain from giving the curves. A sample of the observations, however, may be interesting :—

August 20th.—Pump continuously working.

Pressure in millimetres.	Reading on small sliding cylinder T_2, T_1 remaining stationary.
0·0230	163
0·0041	154
0·0031	166
0·0022	238
0·0020	162
0·0027	140
0·0029	160
0·0038	142

August 23th.—Air being very slowly let in.

0·0327	314
0·0256	338
0·0256	343
0·0765	350
0·1264	328
0·1923	292
1·9000	339
3·5500	341
7·0000	370
760·0000	395

The readings on either day may be compared one with another, but not those on different days. In either case, however, a difference of 100 in the reading indicates roughly a difference of about 1 per cent. in the capacity of the aluminium condenser. It will be observed that, in addition to the constant fluctuation in the capacity for the same small pressure, a result constantly obtained when very small pressures were employed, and which is probably due to the action of the mercury vapour, the capacity, as a rule, appears to be a useless diminution at the capacity at about 0·15 millimetre pressure. To make sure that this was not an accidental result, the air was pumped out again, when the pressure was about 3 millimetres, until it was reduced again to about 0·1 millimetre when the same diminution of capacity at about 0·19 was again observed. Now, although these numbers are merely now given as a preliminary indication of the results obtained by the committee, they are, as a matter of fact, the same as have been pointed out by Dr. G. F. Fitzgerald, of Dublin, as the values obtained for the capacity between about 0·22 and 0·2 millimetres pressure how a current consolidator in those obtained for the Condor's force.

One difficulty not with in the investigation consists in an apparent change in the capacity of the condensers Band C (partly, no doubt, arising from changes of temperature) from day to day. A similar difficulty was met with in the previous investigation made in Japan, but it was overcome by making alternate measurements of the capacity of the closed condenser, C, and of the air condenser, A, throughout the day. In the present case this is, of course, impossible, on account of the large internal capacity of the conductor A, and the considerable quantity of air which has to be kept at a constant pressure. It takes several days to obtain a measure of 0·001 of a millimetre, even although, at the suggestion of Mr. Crookes, indicating apples from a large induction coil (not shown in the figure) are kept passing between the two sets of aluminium cylinders at all times when the pressure is below 0·1 millimetre, and being made. Probably the best method of procedure is that followed on August 20th, the last day of the investigation, viz., first obtain slowly a complete series of measurements of capacity being necessarily made, then admit into the pump, drop by drop, mercury, sulphuric air, and make, during a couple of hours or so, a complete series of measurements of capacity as the pressure rises from, say, 0·001 of a millimetre up to ordinary atmospheric pressure. By this means the fluctuations during performed several times would probably give a fair indication of the true capacity. As it is also extremely desirable that the experiments should be made with electrical charges of considerable electricity, the committee have had constructed a somewhat modified form of Thomson's quadrant electrometer, which they also used in the investigation for the measurement of the specific capacities of the different substances, the second half of their work which they have not yet commenced.

THE SUCCESS OF THE ELECTRIC LIGHT.*

Not a little impatience has been manifested by the public at the seemingly unaccountable hitches with which the work of introducing the "carbon-loop" electric lamp into general use has hitherto progressed. It is now several months since the announcement was made through the newspapers that all the obstacles in the way of the utilisation of the electric light as a commercial and economical substitute for gaslight had been removed; that a method had been invented by which electricity for light or for power could be conveyed to considerable distances economically; that the current could be subdivided almost *ad infinitum*; and that the electric lamp was henceforth to be one manageable for household purposes, was, in fact, at last, so far as the public can see, the project has since that time made no appreciable advance beyond realisation. The lamp was exhibited to the public on the whole with a very fair degree of accuracy, the results expected, on the evidence of the inventor, were obtained, and the Patent Office records have been published their judgment, some of them pronouncing this apparatus to be the doubtered practical solution of the problem of electrical lighting that has been so long sought after. Meanwhile the day when the electric light should be thrown open to the public seems to be indefinitely postponed, and many people are beginning to ask whether, after all, the invention is not, like so many other highly-vaunted discoveries, destined to be a failure. Under the circumstances it was very natural that the unscientific public should begin to ask whether the time had not been imposed upon by the inventor himself or hoaxed by unscrupulous newspaper reporters.

Now, the fact is, that the system of electrical lighting was from the first all that it was originally claimed to be—namely, a practical solution of the problem of subdividing the electric light, and of conveying it to any part of a house, or of several houses, from a central station, by the mains which are required to carry its general introduction are chargeable, not to any defects since discovered in the original theory of the system or in its practical working, but to the enormous mass of details which have to be mastered before the system can get into operation on a large scale, and on a commercial basis as a rival of the existing system of lighting by gas.

With the inventor, no doubt, rests the credit of the first announcement that it was proposed to use, the electric light could have been made available for the lighting of private houses, and that it was in this respect, and in the considerably less cost of the electric light, the lamp would have been rendered comparable as a gas burner. But, fortunately, the unavoidable delay interposed by administrative and economic considerations afforded opportunity for further research and experiment, and the result has been to introduce many essential modifications at both ends of the system—both in the generator and in the lamp; at the same time many hitherto unknown, all in the direction of economy and simplification, have been made at almost every point in the system, as well as in the details of manufacturing the apparatus.

As for the lamp, it has been completely transformed. The external form of the two types of lamp is identical; the principle of illumination—incandescence of a solid body in vacuo—is also the same; but, in the earlier lamp, light was produced by the incandescence of a platinum wire wound on a spool of mica; in the perfected lamp the source of light is incandescent carbon. Another essential difference between the two is found in the form given to the incandescent body: in the platinum lamp it was coiled compactly on a small spool, in the carbon lamp it is a long loop of the finest carbon thread. The platinum spool was found to be incapable of afford a better light for domestic purposes than an incandescent mass of compact form; the shadows it casts are not so sharply defined, their edges being softened.

This loop of carbon is now prepared from the fibre of a millimetre species of bamboo from Japan. A thread of this material, after undergoing a certain chemical process, is bent into the required shape, and then reduced to carbon. The resulting carbon loop is of a remarkably homogeneous structure, and possessed of a high degree of tenacity, so that it can withstand, without breaking, all the concussions it is likely to be subjected to in household use.

The perfected lamp consists of an oval bulb of glass about five inches in height, pointed at one end, and with a short stem three-quarters of an inch in diameter at the other. Two wires of platinum enter the bulb through this stem, supporting the loop or J-shaped thread of carbon, which is about two inches in height. The stem is hermetically sealed after the introduction of the loop. The bulb is then filled with the vapour of mercury, which has been taken through the air in the bulb is extracted down to that of a mercury-gauge till not a trace of air remains in the bulb, which is then sealed in close chemi. The outer extremities of the two platinum wires are connected with the wires of an electric circuit, and at the base of the lamp is a screw by which the circuit is made or broken at pleasure. The circuit is made the resistance offered to the passage of the electric current by the carbon causes the loop to acquire a high temperature, and to become incandescent; but as this takes place in a vacuum the carbon is not consumed. The light is, in fact, produced without any waste of the carbon, continuously varies from seven hours to over sixty in duration between. With an intensified current the lamp is capable of a longer duration of life; and as the average time an artificial light is used is five hours per day, it follows that one lamp will last about six months. Each lamp costs about fifty cents, and when one fails another may easily be substituted.

The light is designed to serve precisely the same purposes as domestic gas, and is, therefore, fitted with a globe, or opaque glass, to modify its intensity, but can be gazed at without dazzling the eyes. The amount of light is regulated by the strength of the current employed. The light is steadier, and consequently less trying to the eyes. It is also purer light than gas, being white, while gaslight is yellow. Further, the electric lamp does not vitiate the surrounding atmosphere by consuming its oxygen, as gaslights do, and discharging into it the products of combustion. The best outlay for the lamp is found to be only one fifteenth of that entailed by a gaslight of equal illuminating power; the glass bulb is not expensive, and will last unbroken for years. Of course, there are accidents or inflexionable pieces to account for. The danger of fire is reduced to nil, with a consequent reduction of the rate of insurance. Finally, the light, unlike gas, is always of uniform quality. A set of meters registers exactly the amount of electricity consumed in each house. Finally, not to enumerate all the advantages which this system possesses over gas-lighting, the lamp can be manipulated even by the most inexperienced domestic servant; nor can the most careless person do injury to himself, to others, or to property, through not understanding its mechanism.

Another important modification of the system, introduced since the latest

---

THE ELECTRIC LIGHT AT THE BRITISH MUSEUM.—The preparations for lighting the British Museum by means of the electric light were completed on the 18th October, and notices were posted on the reading room door that the library would remain open on and after that day till seven o'clock during the winter months. Experiments made have shown that the present lighting will be quite sufficient. Two Jablochkoff candles have been placed in each gallery, some of them consuming this apparatus to be the doubtered practical solution of the problem of electrical lighting that has been so long sought after. On the day when the library was thrown open to the public seems to be indefinitely postponed, and many people are beginning to ask whether, after all, the invention is not, like so many other highly-vaunted discoveries, destined to be a failure. Under the circumstances it was very natural that the unscientific public should begin to ask whether the time had not been imposed upon by the inventor himself or hoaxed by unscrupulous newspaper reporters.

Now, the fact is, that the system of electrical lighting was from the first all that it was originally claimed to be—namely, a practical solution of the problem of subdividing the electric light, and of conveying it to any part of a house, or of several houses, from a central station, by the mains which are required to carry its general introduction are chargeable, not to any defects since discovered in the original theory of the system or in its practical working, but to the enormous mass of details which have to be mastered before the system can get into operation on a large scale, and on a commercial basis as a rival of the existing system of lighting by gas.

With the inventor, no doubt, rests the credit of the first announcement that it was proposed to use, the electric light could have been made available for the lighting of private houses, and that it was in this respect, and in the considerably less cost of the electric light, the lamp would have been rendered comparable as a gas burner. But, fortunately, the unavoidable delay interposed by administrative and economic considerations afforded opportunity for further research and experiment, and the result has been to introduce many essential modifications at both ends of the system—both in the generator and in the lamp; at the same time many hitherto unknown, all in the direction of economy and simplification, have been made at almost every point in the system, as well as in the details of manufacturing the apparatus.

As for the lamp, it has been completely transformed. The external form of the two types of lamp is identical; the principle of illumination—incandescence of a solid body in vacuo—is also the same; but, in the earlier lamp, light was produced by the incandescence of a platinum wire wound on a spool of mica; in the perfected lamp the source of light is incandescent carbon. Another essential difference between the two is found in the form given to the incandescent body: in the platinum lamp it was coiled compactly on a small spool, in the carbon lamp it is a long loop of the finest carbon thread. The platinum spool was found to be incapable of afford a better light for domestic purposes than an incandescent mass of compact form; the shadows it casts are not so sharply defined, their edges being softened.

This loop of carbon is now prepared from the fibre of a millimetre species of bamboo from Japan. A thread of this material, after undergoing a certain chemical process, is bent into the required shape, and then reduced to carbon. décrire, exigent pour donner leurs indications qu'on fasse une expérience spéciale, qu'on les consulte, et il estime qu'on ne les consultera pas. Il voudrait constituer des appareils scientifiques, à l'aide de conduites électriques, de transmettre dans toutes les habitations à un bureau central où une surveillance spéciale serait exercée. Je partage à cet égard son opinion : je suis convaincu qu'un semblable contrôle aurait la responsabilité en engagée, offre vingt fois plus de sécurité qu'on ouvrier qui est lui-même chargé de protéger sa vie. Rien n'égale l'incroyable imprudence des hommes dans une besogne habituelle, et un système d'avertissement centralisé serait certainement tout à fait précieux.

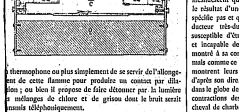
Malheureusement M. Somzée ne fait qu'indiquer des moyens de réalisation ; il est vrai qu'il en propose plusieurs, notamment pour l'aide, comme de faire agir la flamme des lampes à sécrété sur une plaque téléphonique fonctionnant comme



thermophone ou plus simplement de se servir de l'allongement de cette flamme pour produire un contact par dilatation ; au bien il propose de faire détonner par la lumière le mélange de chlorure et de grisou dans le bruit serait aussitôt téléphonique.

Tout cela, ce sont des idées jetées un peu en l'air, et cela ne se peu un seul appareil d'utilité ; ce qui me paraît réellement pendre en considération c'est l'idée de la centralisation des fications ; il y aurait lieu, ce me semble, de chercher dans ce voie.

FRANK GÉRALDY.

REVUE DES TRAVAUX

RÉCENTS EN ÉLECTRICITÉ

Perfectionnements apportés aux lampes à incandescence.

On doit se rappeler que dans plusieurs de nos articles pu- s sur la fameuse lampe de M. Edison (voir p. 19 et 93), ons dit que l'idée d'employer du charbon de paper n'a fait être rougir dans le vide avait été conçue et expérimentée lampes avant M. Edison par M. Swan; nous avons même que ajouté que les premières expériences de celui-ci n'- pas été très-heureuses, mais qu'il était sur la voie de lopter les difficultés qu'il avait rencontrées (voir la note de page 59). Or nous lisons dans l'*Electrician* que, le 20 oc-

tobre dernier, ce même M. Swan, dans une conférence faite à la Société philosophique et littéraire de Newcastle-on-Tyne, est parvenu à des résultats tellement avantageux qu'il croit ce système de lampes devoir résoudre pratiquement l'éclairage domestique. Quoique n'étant pas encore convaincu de l'importance de ce système, nous devons cependant convenir, d'après la manière plus sérieuse dont la question se trouve traitée par ce savant, qu'il y a un perfectionnement réel accompli, et que la lampe se trouve sensiblement dans de bonnes conditions de durée; mais bien que M. Swan fasse de très-heureux rapprochements pour prouver que la division de la lumière par ce système est économique, nous avons besoin d'expériences plus complètes pour être convaincus. Nous discuterons, du reste, le mémoire de M. Swan, car évidemment on commet toujours à ce sujet des confusions regrettables qui induisent souvent le public en erreur.

Quant aux perfectionnements signalés par M. Swan, ils consistent principalement dans la préparation du charbon employé et qui n'est plus du charbon de papier, mais le résultat d'une agrégation de matières carbonisées qu'il ne spécifie pas et qui aurait l'avantage de fournir un semi-conducteur très-dur, très-homogène, tout à fait infusible, susceptible d'être dévié en un ruban excessivement mince et incapable de se désagréger dans un vide parfait. Il a montré à sa conférence plusieurs échantillons de ces lampes, mais comme ce n'est qu'à la longue que ces sortes d'appareils montrent leurs imperfections, nous ne discuterons pas ce que d'après son dire. Pour éviter les effets de la rentrée de l'air dans le globe de la lampe, sous l'influence des dilatations et contractions des charbons métalliques qui amènent ce fait à chevel de charbon, il recouvre celles-ci de verre sur presque toute leur étendue, et ω. sont ces manchons de verre qui sont soudés dans le globe lui-même. Souvent les tubes de Geissler sont disposés de cette manière, mais nous ne voyons pas pourquoi les effets de dilatation et de contraction seraient évités par ce moyen. C'est pourtant là le point important, au dire de M. Swan lui-même, car il attribue à cette circonstance la non-durée des essais faits jusqu'ici. Il paraît de ce qu'il avance, il fait l'historique de toutes les expériences exécutées par lui à différentes époques depuis vingt ans, et ces historiques présente un réel intérêt.

Lors de ses premières expériences, il employait une spirale de carbon carbonisé qu'il plaçait entre deux blocs de charbon à l'intérieur d'une ampoule de verre dont on fit les moyens peu perfectionnés que l'on connaissait il y a vingt ans, et il s'aperçut, à son grand étonnement, que le courant n'est pas le charbon de Cailho, traversait cette spirale, sans se la faisait pas même rougir. Il attribua cet effet à ce que la spirale présentait trop de résistance, trop de surface de rayonnement et à ce que la pile n'était pas assez énergique. Il répéta alors l'expérience avec un charbon moins développé et en forme de fer à cheval; c'était exactement la disposition de M. Edison ; il mit à contribution une pile de 40 éléments, et il obtint de cette manière un effet calorifique assez intense pour faire rougir son charbon; mais il constata bientôt que celui-ci se désagrégeait et fournissait des va-

Maxim's Automatic Regulator for the Electric Light.

In previous articles descriptive of the improvements in electrical machinery devised by Mr. Hiram S. Maxim, we have referred to his self-regulating lamp. This is a very important element of his electric lighting system, and, as will be seen below, the devices which he employs meet the difficult conditions of the case in a very ingenious and practical manner.

The principle upon which Mr. Maxim has proceeded in the construction of his regulating apparatus, is to utilize the electric current itself to feed the carbons. No purely mechanical device can be successfully used for this purpose, since with all the care that may be bestowed in making them, it is quite impossible to produce carbon poles that will be perfectly uniform in

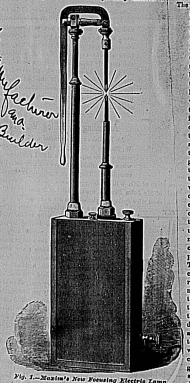


Fig. 1.—Maxim's New Focusing Electric Lamp

composition, and the slightest difference in density or homogeneity at once affects the passage of the current, and consequently the steadiness and brilliancy of the light. The poles also, by wasting away irregularly, throw the light out of center. It is obvious, therefore, that any regulator for the electric light to be successful, must operate on the principle of controlling the feed of the carbons by the electrical current itself, and the regulating devices must be so accurately constructed and so delicate in action, as to be sensitive to any trifling variations in the carbons themselves, so that their motions shall be controlled within very narrow limits.

An inspection of the accompanying engravings in the following description, will show how fully Mr. Maxim has comprehended the difficulties we have pointed out, and how ingeniously he has met and overcome them. In the engraving, Fig. 1 represents a perspective view of the lamp and Fig. 2 a section through the case, exhibiting the regulating mechanism. Referring to Fig. 2, A and B are tubes in which the carriers of the positive and negative carbons respectively operate. The positive carrier A is provided with a rack, partially seen in the cut, and which engages with a train of toothed wheels. The lower end of the negative carrier is provided with a pulley D, whose movement is controlled by a cord that is lengthened or shortened by the movements of the train of gears that actuate the positive; E is the coil of an axial magnet; G is an adjusting screw which determines the length of the voltaic arc; and F is a stop for arresting the train of wheels when the light is extinguished.

The action of this regulator is as follows: Connections having been properly made, the positive carrier is drawn up to its highest position and the carbons inserted in their respective holders. The weight of the positive carrier causes it to slowly descend, carrying the positive pole with it, and setting in motion the train of gears. At the same time, the cord of the pulley from which the negative carrier is suspended, is wound up, carrying the negative pole upwards, until the combined movement of both carriers brings the poles in contact. This completes the circuit, and the current at once commences to pass. At the same instant the helix is excited the coil E is drawn downward. Being attached to a detent, this downward motion of the coil E looks the gearing, and at the same time it draws down one end of the cord which sup-

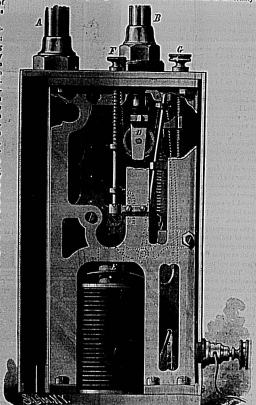

Fig. 2.—Movement of Maxim's Lamp.

ports the negative carbon, which likewise slightly descends. The trifling separation of the two poles by the descent of the negative pole, establishes the voltaic arc, and the lamp is lighted. As the carbons are consumed, the resistance becomes greater by the lengthening of the arc, and the power of the current to excite the helix is correspondingly diminished. The excitement of the helix is lessened, and the coil E is drawn upwards by the pull of a retractable spring seen in the engraving, the session of which is adjustable, to insure extreme delicacy of action in the apparatus, and which the coil is no longer able to oppose. The spring pulls the coil upwards until the detent unlocks the gears, thus setting the train again in motion, and causing the carbons to approach each other as before described, until the arc is sufficiently shortened, when the current, having been restored to its original strength, again draws the coil downward and locks the gears. The construction of this ingenious regulator is so accurate, and the adjustment of its parts so nicely effected, that the locking and unlocking of the gears is accomplished by very trifling variations in the electro-motive force of the current, and consequently the movement of the carbons is controlled within very narrow limits.

From this description, it will appear that Mr. Maxim's regulator is perfectly automatic in action, and controls the light by means of variations in the intensity of the electric current, whether these proceed from the consumption of the carbons and the consequent lengthening of the arc, or from want of uniformity in the carbons themselves. It is claimed, as a proof of the superior delicacy of this form of regulator, that tests have shown that machines of all makers run lighter on this lamp than on any other, and with much less fluctuation of power.

Further information may be had on application to the United States Electric Lighting Company, 199 Broadway, New York.

THE ELECTRIC LIGHT.

THE Sun Electric Light Company have acquired a patent for the manufacture of fexible carbon—a very important advantage, as it can be rolled up and stowed away in a small space—and they are about to use it in the patent lamp at the Crystal Palace. If the experiment answers, it is anticipated that the new Palace will be lit up in the same manner. The Agricultural Hall at Canterbury is to be lighted next year by the same company.

The London correspondent of the *Liverpool Daily Post* writes:—Some important information has reached me on the nature of Edison's electric light. It is formed by a coil of platinum being placed over a wire heated by the electric current. The coil itself is the source of light, the current sent through it being just enough to make it white hot and self-luminous. The difficulty to be overcome at this point of the invention was the melting of the wire to fuse, and spoil the light—a difficulty which Mr. Edison claims to have obviated by the introduction of a simple device, which, by the expansion of a small bar the instant the heat of the coil approaches the melting point of the platinum, interposes a check to the flow of the current through the coil." Mr. Edison can raise and lower each light independent of the others, and is also said to have effected an improvement in the burner by which the amount of light with the same power can be doubled. The discovery was the result of pure accident. He swore that on his plan, when a light is turned out its extinguishment immediately regulates the force of the current, so that only enough is supplied to keep the other burners burning. He can already measure the current used, and intends to divide his 300-candle power so as to make it seem as reliable than the 1,000-candle power of a carbon-point lamp.

Mr. G. William Siemens, on December 12, wrote:—"I may comparison between the cost of the electric current and its rival, gas, must be limited until central motor stations are established in populous districts, where motive power may be produced at the cheap rate of 1lbs. of coal per horse-power per hour, and whence radial conductors may supply the neighbourhood within, say, a mile radius, with both light and also with mechanical power for minor industrial purposes. It is well known that in order to produce the electric light cheaply it should be effected in as concentrated a form as possible, the reason being that the light increases in the square ratio of the current employed. The same reasoning points to the fact that extreme sub-division of the light for domestic purposes must be attended with great loss of effect."

An experimental illumination of the Thames Embankment has been made by the Société Générale d'Electricité, of Paris. Sir James Hogg, M.P., Chairman of the Metropolitan Board of Works, and Mr. Joseph Bazelgette, engineer, witnessed the display, which they pronounced highly satisfactory. Ten lights were used between Westminster and Charing Cross Bridges. The putting up of the electrical apparatus was carried out under the direction of M. J. A. Berly, engineer to the Paris company, and the contract has been executed by Messrs. Wells & Co., of Shoreditch. On the following evening the electric light was experimentally tried upon the Holborn Viaduct. The system used was the Jablochkoff, and the battery was driven by a 20-horse power engine, constructed by Messrs. Bisbey. The light was remarkably steady and brilliant, and about one-fourth of the lamps used in the ordinary way were required. The trial, it is understood, will be continued for some time, and arrangements are being made to light the Royal Exchange and the Mansion House by the Wendermann, so as to afford the public an opportunity of comparison. An interesting experiment in street-lighting by electricity on a practical scale is also in progress at Westgarten-See. The system adopted is that of M. Jelbochkoff, and there are six lamps, carried on standards 9 feet high, and placed 80 yards apart, their situation being the sea road, which is laid out on the curve. The trials hitherto made were very successful. The contractors for the supply of the electrical apparatus, cables, and lamp fittings, are Messrs. J. Edmondson & Co., of Westminster.

The electrical light is to be adopted by the Royal Carriage Department at Woolwich Arsenal, in a large building known as the mounting-ground.

Messrs. Shoolbred have had their establishment in Tottenham Court Road partially illuminated with the electric light, and so satisfied were they with the result that it is said to be their intention to use it in every department of their business, both inside and outside. Messrs. Wells & Co., of Old Street, Shoreditch, have the management of all the engineering portion of the work.

The North-Eastern Railway Company have just introduced the electric light with great success into their large engineering works at the South Dock, Sunderland. The light burns night and day, and is much preferred to gas by the workmen. It is understood that, owing to the success of the introduction, the company will shortly extend the electric light to their other works in the North.

Mr. Edison, according to the latest American papers, has completed his lamp, and is now at work to ascertain the description of generator that will produce the greatest amount of electricity per horse-power. It will be several months before he can make a public exhibition of his light. He has obtained several patents, but he will not take them out until he has completed his invention.

Ironmonger. May 10, 79.

THE ELECTRIC LIGHT.

MR. W. H. PREECE on Wednesday evening delivered, at the Albert Hall, the inaugural lecture on the Exhibition of Electric Lighting Apparatus. The Prince of Wales, the Duke of Edinburgh, and a large assembly of ladies and gentlemen were present. The Westminster Hall was one of the first shown, and while it lasted, was both bright and steady. Much attention was also excited by the light produced by brilliun rendered incandescent by electricity, and much satisfaction was expressed at its extreme brightness, purity, and steadiness. The Jablin light also made a brilliant show, and the Lane-fox was greatly admired on account of its steadiness. Then came the turn of the so-called "candles," comprised on the systems of Jablochkoff and Wilde. The forms of these, ranged round the upper corridor, for an instant shone brightly, but afterwards gave evidences of capriciousness. On the other hand, the Wilde lamps, from their being close together instead of distributed over a wide circuit, or from some other cause, burned very steadily and well. Mr. Preece then introduced the audience to the "Swiatoshaw," a powerful lamp for "filtering the depths of the sea," about to be introduced into the ports at Spithead, with a view to testing their value in protecting the advance of an enemy's torpedo. He next referred to the advantage of the "arc" over the "incandescent" system in economy of power, and the strength of the incandescent lamps in their great steadiness and durability. The Wallace-Farmer lamp was then tried, with very satisfactory results; and the eyes of the audience were next directed upwards towards the great Siemens light, or rather chandelier, hanging from the inside of the dome, and which made a noise far less agreeable to the ears than the light was to the eyes. Mr. Preece dwelt upon the many shortcomings of the electric light as at present produced—the noise, the flickering, the deep shadows, and the whiteness of a light which sets all calculations based upon the warm yellow of gas-light at defiance. On the other hand may be set the absence of smoke and the nutrition instead of the poisoning of the air in large buildings.

N.Y. Herald, June 19, 80.

The Electric Light as a Preventive of Collisions.

The great question raised afresh by the late steamship collisions is the availability of the electric light as a preventive of such disasters. But if the utility of the invention is not now settled while the public is agitating the question shipowners and shipmasters will be likely to dismiss it till another Narragansett goes down. Despite the prejudice in the minds of seamen against every innovation in their ancient craft, the electric light strongly commends itself for use by passenger steamers, especially while moving through thick fog. The trite objection which some nautical men urge against it is that its brilliance obscures distant objects lying on the ship's path, but not within the circle of dazzling illumination. But this is without force, since in many fogs the opacity of the air entirely conceals all objects a ship's length ahead, and, if the navigator is steering by the compass, it must frequently happen that he will be in positions where the view of distant objects is for the time of no consequence, while the view of an object near or nearing him is of vital importance. The electric light, by proper manipulation, is confessedly capable of irradiating the entire area of danger, and this is all that is necessary for a vigilant captain. The Select Committee of the House of Commons a year ago reported—"So far as the practical application of the electric light has gone, there seems to be no reason to doubt, it has established itself for lighthouse illumination." But if its range of beam is as great as to warn vessels of high speed from running on a sunken ledge why should it fail to warn them against collision?

In 1877 the steamship Faraday, while moored at Gravesend, previous to her voyage to America, was illuminated by the electric light which she carries—an intensely brilliant light, equal to about five thousand normal candles—placed near the bridge, and persons on shore, nearly a third of a mile off, could see to read ordinary writing with perfect ease. "A vessel carrying so powerful a light," as the London *Telegraphic Journal* forcibly says, "is better able to sight any distant objects on dark nights, and she herself can be sighted even by other ships; the electric light thus provides a ship with a better safeguard against collision." The Faraday's powerful light only absorbs about three and a half horse power, used by a small steam engine placed on deck. The English war ships *Temeraire*, *Benedmeight* and others are similarly equipped with electric lighting apparatus, and if they can employ it to advantage why may not merchant ships? Doubtless the chief use to which the light is put is to prevent collision in dense fogs; but experience shows that even on a clear night at sea collisions occur from mistakes that could hardly be made if either endangered vessel was electrically illuminated. At two o'clock in the morning, November 22, 1873, with fine weather and the night starlight, the Ville du Havre was fatally run down by the Loch Earn, an English ship, both vessels, as all the testimony shows, carrying the well-trimmed colored lights required by law, and the French report stated that the Loch Earn was seen by the other ship three and a half miles off. As this is one of the most familiar and disastrous of modern collisions its voice should still be heard, demonstrating that the most skilful mariner at night—clear though it may be—needs all the artificial light he can get to avoid the fatal crash.

SEPTEMBER 6, 1882.
THE STANDARD,
DOMESTIC ELECTRIC LIGHTING.

(FROM OUR CORRESPONDENT.)

NEW YORK, TUESDAY NIGHT.

Mr. Edison's system of providing an incandescent electric light for use in a given district has just been put to a practical test in this city. The district selected comprises an area of nearly a square mile. Only one source of supply is provided, and that furnishes the illuminating power for sixteen thousand lamps, the electric current passing through eighteen miles of mains. The result is that the soverest demands which the consumers have been able to make upon the new system have been satisfied.

The *New York Herald* is using in its business premises an isolated plant on the same principle; and the managers assure me that they are satisfied in respect to the commercial aspect of the question.

No new obstacle has presented itself to the success in practice of Mr. Edison's theory; and scientific men will be interested to know that this first practical experiment demonstrates the soundness of the inventor's application of the multiple arc system, pure and simple, as distinguished from the series system, or the combination of the arc and series systems.

Throughout the entire district lighted as described, each lamp was independent of all the others. On the inquiry before the Select Commission of the British House of Commons, Dr. Siemens said it was impossible to apply electricity for domestic lighting, from one source, over a greater area than a square quarter of a mile. Last night, although only five thousand lamps were lighted, they were distributed over the entire district of the square mile. In the district there are fifteen hundred consumers of gas, of whom eleven hundred have subscribed for the electric light.

N.Y. Herald, March 27, 80.

The press interest which is now being felt throughout the civilized world in the economy of the various sources to light homes by electricity, together with the contradictory statements made with respect to Mr. Edison's method, have induced us to attempt a brief examination of the efficiency of his lamps. We have chosen this important because most of the information on the subject has not been given to the public in a trustworthy form. We have endeavored to make a test but constitutes—test of the efficiency of the light—that is, the amount of light which could be obtained from the horse power of work given out by the steam engine. For if the light be economical the minor points, such as making the carbon strips last, are undoubtedly be put into practical shape. Three methods of testing the efficiency presented themselves to us. The first was by means of measuring the horse power required to drive the machines, together, with the number of lights which it would give. But the dynamometer was not in very good working order, so it was difficult to determine the number of lights and their photometric power, as they were continued throughout a long duration, and no one disturbed. Another method was by measuring the resistance of and amount of current passing through a single lamp. But the instruments available for this purpose were very rough; and so this method was abandoned for the third one. This method consisted in heating the lamp under water and observing the total amount of heat generated in the water per minute. For this purpose a calorimeter, holding about one and a quarter bitumens of water, was made out of very thin copper; the lamp was held firmly in the centre, so that a stirrer could work around it. The temperature was noted on a delicate Beckin thermometer graduated to 0.1 C. or 0.2 F. As the experiment was only meant to give a rough idea of the efficiency within 10 or 15 per cent no correction was made for radiation, but the error was avoided as much as possible by having the room temperature of the calorimeter as near that of the air as possible; and the loss by evaporation under the error would then be small. The following table will show the results of the experiments. In the seventh column the total amount of heat generated in the water, in the calories of energy must have been very minute. In order to obtain the number of units of work done by the engine and machine two points were generally used, one being in the vicinity of 1,000 and the other of 1,500 revolutions per minute. The mean of the two results was then taken. The apparatus for measuring the light was one of the ordinary Bunsen photometers used for determining gas lights, with a grease spot on paper, and a standard candle placed on one of the ordinary candlesticks. Two points per burner. They were retained before and after each experiment, but no change was observed. The standard candle was placed two feet from the grease spot before comparisons were made.

As the ratio of carbonized paper was fat very much more light was obtained at the expense of the carbon strip which burned there. In the prime of the lamp? Two observations were taken of the photometric power—one by a dynamic [illegible] to

NEW YORK HERALD, THURSDAY, OCTOBER 17, 1878. TRIPLE SHEET.

ELECTRIC LIGHT.

The Invention Discussed by Members of the American Gaslight Association.

IS IT PRACTICABLE?

A General Impression that Gas Will Not Soon Be Blown Out.

The American Gaslight Association met yesterday in the Fifth Avenue Hotel at the fifth annual convention. About one hundred members and forty-five members were present, among whom were delegates from most of the large cities. Nominations for officers were made, the President, General Charles Stewart Smith, occupying the chair. The following officers were elected, for the ensuing year:—President—Charles Stewart Smith, New York. Vice Presidents—H. Price, Cincinnati, Ohio; Charles Smith, Boston, Mass.; Secretary and Treasurer—Charles Hodenpyl, New York. Executive Committee—Richard B. Dennison, Philadelphia, Pa.; George S. Cahill, Lawrence, Mass.; A. Hewlett, Brooklyn, L. I.; Henry Cartwright, Philadelphia, Pa.; F. G. Sherman, New Haven, Conn.; Henry Sherry, Indianapolis, Ind.

IN GENERAL SUSPENSE.

Shortly after twelve o'clock a recess was taken until two o'clock in the afternoon. During this interval and after the adjournment in the evening the members discussed the practicability of the electric light for illuminating use.

"I have witnessed experiments made with the electric light," said Mr. Henry Cartwright, of Philadelphia, "and I am very confident about its having been perfected. The Exposition Building in our city has been lighted by it, and I am sure that gas would have been far more efficient and satisfactory."

PROFESSOR SMITH'S OPINION.

"You have not much faith, then, in the success of Mr. Edison's invention? You think it is impossible to so widen the electric to serve cities?" he was asked.

"No, I do not say that. Of course I do not know anything about his invention, and I cannot comment in writing saying it. But it seems to me that he fails to measure properly the great excellence of using electricity for illumination. It is very easy to say that each burner or lamp will cost only so much per day or hour; but I really think that he is ignorant of the actual advance or his proposed system. Gas companies have been in existence for years, and people are very accustomed to come to their centres almost exclusively. They are ready to believe almost anything in reason that is told them, and I am sure that gas companies have more confidence in their system than ever."

Mr. Henry Sherry, of Indianapolis, added—"He has not been here to-day, and I do not like to express an opinion in his absence. Besides, I have not had any experience with Mr. Edison's electric machine. The light was very brilliant and powerful, as it certainly must be, as each one was to take the place of 2,000 gas burners. I am very much interested in Mr. Edison's invention although I am unable to pronounce upon it."

"Do you," the reporter said to Professor Smith, "believe that the electric light can sustain itself in competition with gas?"

"I think, however, that your question is premature. I have not had any experience with the electric light, and I am not prepared to say. I am sure that Mr. Edison is a man of great ability, and I am sure that he has done all that he could to perfect his invention. I am sure that he has spent a great deal of money, and I am sure that he has had the most intelligent people were most interested in it."

"Do you think that the electricity will finally supersede gas as an illuminating agent?"

"That is one of those things that no living man can tell. I have no doubt, however, that the electric light will have a great many uses, and in one respect I think that it will surely be preferred—at least the use of it will prevent the explosions of gas. Whether it will or will not be the gas successor, of course, I cannot say. I am sure that the electric light will never be introduced as cheaply as gas."

"The question of cost is an exceedingly difficult one," said Mr. Hodenpyl, of the Edison Company, "and one which we have not yet considered."

Mr. R. S. Greenleaf, of the Boston Gas Company, said:—"I have had no experience with the electric light, and I do not think that I have sufficient right to say just much. I understand, however, that Professor Farmer, of the Boston Public Library, has had the electric light for two years, and considers the invention of Mr. Edison's a great improvement upon the old system. I have also been told that Professor Farmer says that the electric light is very much cheaper than gas. I understand that Professor Farmer has just summed up the comparative cost of the two lights, and that he finds that the electric light costs but one-half as much as gas. I understand that Professor Farmer will soon publish his statement."

Mr. Greenleaf, in response to a question, said that he could not say whether the electric light would be introduced as cheaply as gas.

Mr. Hodenpyl, of the Edison Company, said:—"I have no doubt that the electric light will be introduced as cheaply as gas."

The discussion of coal in an exceedingly difficult form which to burn and in its relation to gas was then taken up.

Mr. R. S. Greenleaf, of the Boston Gas Company, said:—"I am not prepared to say which is the best coal for gas purposes. I have been in the business for ten years, and I have always been in favor of the cannel coal. For coal, cannel coal contains a greater percentage of illuminating power than any other coal. I have used the Pittston coal for the past summer for the purpose of enriching the gas, and I find that it is a very good coal. I have also used the Cumberland coal, and I find that it is very good coal. However, its cannel the cannel coal."

THE ELECTRIC LIGHT DISCUSSED.

The Gaslight Society is evidently despised as a failure—not only the future, as Master Professor Farmer has said, but also and heretofore by planter of Price and Edison. Professor Farmer, of the Boston Public Library, has had the electric light in use for two years, and it was used in October and ten inches long. They are to be used in the Exposition Building in our city and have been used in other cities, and the electric light. Proof of these are usually fixed on a stand which an operator can move at will. The light is produced by a current of electricity passing between two points of carbon. They cost twelve cents each.

Mr. Greenleaf said that gas companies themselves could not be interested. One, he thought, would be in the case against any other illuminating material.

At the afternoon session of the association Mr. Charles Stewart Smith, of New York, was elected President, and Messrs. Greenleaf and Sherry as Vice Presidents. Mr. Hodenpyl read one on "Gas Meters in Lecture Rooms," which was followed by a discussion of the necessary precautions to be taken in the use of gas in lecture rooms. It was shown that under these circumstances the meters were not to be used, but meter meters for the amounts, many, one for and one for the lecture room. The meeting then adjourned to meet in Boston on the third Tuesday in October next.

EDISON'S VIEWS ON ELECTRIC LIGHT.

At the close of the session adjourned until to-day. This evening it will proceed to a body in the Fifth Avenue Hotel, to-morrow, and listen to a paper by Professor Morton on the electric light. The lecture will be illustrated by experiments. Mr. Edison will be present to explain his methods, so that by attending this the public will be afforded an opportunity of seeing the light which is so far that the secrets of the inventor will be revealed. Professor Morton's lectures are always interesting, and the experiments which he will make will be extraordinary exhibitions of skill and electrical knowledge.

The gentlemen authorized to Engineer have thrown a flood of light on the electric light in connection with Edison's invention. Mr. Edison's 1,000 candle power light is equal to that of 2,000 candles, and is produced by 2,000 burners. Mr. Hoppenstedt Pennington, one of the directors of the Edison Company, explained the principles of the electric light machine, &c.

The electric light does not interfere with gas light, nor does it affect the telegraph wires.

The electric light is produced by the current passing through a carbon burner, and in case a gas is used, the electric light is produced by the current passing through a carbon burner, and in case a gas is used, the electric light is produced by the current passing through a carbon burner, and in case a gas is used, the

EDISON'S ILLUMINATORS.

THE STREET, DWELLING, SHIP, AND MINE TO BE ILLUMINATED BY THE ELECTRIC LIGHT.

DR. GERMONOT'S LAMP—THE INCLOSED SYSTEM.

IN SUCCESSFUL OPERATION.

The Edison "electric illuminator," with the Crystal Palace system of lighting, is now completed the lower quarter of the city. There was a strange glow last night, but it was not the glow of fire, but a mild and distributed light more and uniformly diffused, unaccompanied by a steady, plain, bright and intense, which, illuminating, interiors and leaves shadowy, mysterious, and indistinct exteriors, and produces darkness these points of light looked like drops of dew suspended from leaf and petal, or hail in every moment." Many accruing by in the processions of the moment. Many "lamps," but, let the attention of those who have not to-day almost the eye was at once arrested, it was the flickering of the flaming lamps of Edison, and not shining by the side of the pendulum, but in the middle of the top of the Districts into which the city has been divided. The flaring, white the time was the experiment then the regular inauguration of the system, which was to occur on the 15th. Still there had been considerable interest and curiosity, and the darkness was sufficient to send to the west of the Wizard of Menlo Park's discovery that the practical application of his invention would be of the "great, the most, the most" ever conceived of (Ah,) the most wonderful and the luminous housetops did not work well. For a long time the engineers have been at work preparing for the lighting of the district, and the dynamos and the engines which are to furnish the motive power have been in position and fast time to be attended to, and then came the unlooked for delay. The Edison Illuminators. As there was but one completed expert workingman in the city, Mr. Edison, who has been at work building powerful machines in place, where the lighting apparatus is not yet ready. Then, too, the wires which are to carry the light to all parts of the city and its vicinity, have been a long time. So, many people shook their heads at failure to-day, and said that the whole thing was premature. With the exception that no fuss was to be observed, and engine was very near to fuss to go wrong, the American Bethesda, by turns, was as still as could be expected. Some of the men and all engineers in the immediate, and had screwed, if not all tightened, that "electricity would eventually entirely supersede steam upon railways." Mr. Edison, who has held a few words upon the subject of Mr. Edison himself and the health criticism which he had received. Something had been said, about his selling his shares in the Edison Company, and he was asked if he intended to go abroad. In response to remarks, that Mr. Edison was in such matters one of the most single-minded of men, and had never bought or sold or had any interest in any gas shares. As to his selling his shares in electric company, it was not until the last year that he had parted with any of them, and then he had only sold a few shares. He had not sold any shares since 1880, and he never thought of it and established. Asked from which he had undertaken to supply the whole world with electricity, Mr. Edison said:

"I am not prepared to say that I have undertaken to supply the whole world with electricity, but I have undertaken to supply the whole world with the electric light, and I am prepared to do it. I have undertaken to supply the whole world with the electric light, and I am prepared to do it. I have undertaken to supply the whole world with the electric light, and I am prepared to do it.

London Daily News, Aug. 24, 82.

Address which was delivered yesterday by Dr. SIEMENS, as President of the British Association, was of a more technical and personal character than is usually to be found in those compositions. It differs as widely as possible from Sir JOHN LUBBOCK elaborate disquisition of last year, and from the impassioned harangue to which Professor TYNDALL declared that he dreaded no matter the force and potency of every form of life. Dr. SIEMENS, from beginning to end of his remarks, stuck to business. The idea of his life, as Sir JOHN LUBBOCK happily said in resigning the chair to the new President, has been to economise energy, and to make use of the forces of nature. His is well known as among the foremost, if not the very first, of the pioneers of electrical engineering, and on that topic he had much that was interesting and important to say. But he did not confine himself to his own more special subject. A review of the advance which science has made during the year is the staple product for the manufacture of Presidential addresses, but Dr. SIEMENS has been content to consider science chiefly, if not solely, in its applications to social and commercial purposes. Sir JOHN LUBBOCK, presiding at the jubilee of the Association, found a magnificent subject provided for him in a retrospect of fifty years' scientific progress. The second half-century of this time most famous of annual congresses is opened with a series of illustrations of the utility of science, from a distinguished practical experimentalist. It may be that this fact is typical of a change notable the Association itself. So far as such things can be foreseen, the present generation may be said to stand upon the verge of a material revolution to be wrought by science. Among the many thousands who visited the Electrical Exhibition at the Crystal Palace last spring, there must have been not a few who, as they contemplated that vast expanse of artificial daylight, felt that the human mind had achieved a new conquest over nature. The marvellous improvements in the transmission of sound, the telephones, the phonographs, the mouthphone, the photophones which have come into being alongside of the electric light and the electric railway, and the other new modes of applying force conquered only yesterday, open an almost boundless prospect of distance abridged and power economised, and the mechanism of life transformed. It is but natural that at such a time, as in the Jesuolan age, men should look upon science rather as a source of practical improvement and assistance than as a method of elevating the mind, and leading it, as PLATO said, to the study of abstract truth. The boundless ardour of scientific speculation, the limits of positive knowledge, form a subject on which physicists when they are compelled to be more or less popular, and desire to be more or less profound. But a President of the British Association who descends to humbler themes deserves respect for his courage and gratitude for his pains.

"Electricity," says Dr. SIEMENS, stands foremost amongst the exact sciences." In "ultimate nature it is wrapt in mystery," but its latest developments are within the knowledge of all. It is a "mode of motion," the heat and light, and it is the form of energy best suited for transmitting an effort from one place to another." Among the most interesting and curious uses of the force it is practically applicable to agriculture. After two years' experience Dr. SIEMENS is able to say that "economical transmission of power seems well adapted for effecting the various operations of the farm and fields from one centre." The wonderful influence of the electric light in ripening plants has been described on previous occasions by Dr. SIEMENS himself. It will be found from his Address that corn so treated came to maturity in less than half the time required by that which was ripened in the ordinary way. There is an electric railway now being constructed in the North of Ireland, which when completed will be twelve miles long. The electric current is to be communicated by a separate conductor, returning through the rails themselves. Dr. SIEMENS is not, however, disposed to believe that this new locomotive power will in its present condition supersede steam on ordinary lines. The Address sums up the advantages of the electric light in a convenient and compendious form. In the first place, electricity does not, like gas, give out products of combustion which heat the room and poison the air, and its carbonic acid and compounds of sulphur. Being as rule white, instead of yellow, it does not by altering equally the appearance of flowers and pictures, as indeed most people have by this time had the opportunity of deciding for themselves. Its effect upon growing plants is, it has been already observed, salutary, whereas the result of other artificial light exhibited in their presence is injurious. The difficulty of keeping steam engines continually at work for the supply of the light is, as Dr. SIEMENS explains, being gradually overcome by the introduction of the secondary battery, which discharges analogous functions to those of a gasholder. How completely in its infancy the question of electric lighting still is may be seen from Dr. SIEMENS' remark, not now made for the first time, that "the electric light may be worked by natural source of power, such as waterfalls, the tide, wave, or the wind, and it is conceivable that these may be utilised at considerable distances by means of metallic conductors." It is somewhat surprising therefore to read that, in Dr. SIEMENS's opinion, "gas-lighting will hold its own as the 'poor man's friend'." Dr. SIEMENS believes that gas has a great future, before it, not only as light in improved burners, but also as fuel. In an interesting digression on the composition and sense of London fogs he arrives at the conclusion that the social nuisance and sanitary danger will not be removed, nor even seriously lessened, so long as raw coal continues to be burnt in grates.

Passing from the subject of light, Dr. SIEMENS devoted the remaining portion of his remarks to the recent progress of engineering science. In such a sketch the Panama Canal naturally fills a prominent place. We have, therefore, unfortunately consolatory, and not critical now, the unbearable pretensions which have been put forward by the Government of the United States in respect of the projected waterway. The project itself is a splendid one, well worthy of the genius of M. DE LESSEPS. If it were constructed, it would be the shortest route between England and Japan, and to the whole of the Pacific would be reduced by 3,000 miles the present length of the journey. The sum of twenty millions, the estimated cost, has already been subscribed, and the principal difficulty is one of detail. The engineers who have been employed are said to have perished in great numbers, though on this point there is, we believe, some conflict of evidence. Whereas M. DE LESSEPS, now "dead," left the "best" behind him, Dr. J. GARRETT WILLIAMS, who has just left Egypt, may visit the site of the new enterprise himself. M. DE LESSEPS's third plan, the flooding of the Oasis-Algerian Chotts, or, as it is otherwise described, the re-establishment of the ancient Lake Triton, has not yet assumed a practical shape. Dr. SIEMENS, of course, commemorates the opening of the completed tunnel through the St. Gothard, whereby Italy is directly connected with Switzerland and the South of Germany, and the world scarcely have passed over without notice the projected tunnel under the British Channel, which has been indefinitely postponed. Prudently abstaining, on such an occasion, from political or quasi-political controversy, Dr. SIEMENS confined himself to the single observation that "a strategical point of importance" grew "dull" "minimised the engineering difficulties," but spoke favourably, nevertheless, of Mr. JOHN FOWLER's plan for taking trains across on large ferry boats. Some of the most formidable of the objections have been or could well be raised. The invention by a Cornish Professor of a gunpowder which "resists the action of water, and need not, therefore be kept dry, may live to be the death of the scheme. Such are the main facts contained in Dr. SIEMENS's exhaustive summary. They are stated briefly and simply, without rhetorical flourish or literary embellishment. But their effect upon the imagination

London Daily News, July 11, 82.

ELECTRIC LIGHTING IN THE CITY.

It had report to the Streets Committee of the Metropolitan Board of Works, that they had received notice of the intention of the experimental engineer of the Brush Company to light up, for the purpose of the investigations he was about to undertake, the Thames Embankment, from Westminster Bridge to the Temple, with the electric light on the night of Monday last, and that the Chief Engineer had, in consequence, given instructions to the contractor, and the gas lamps were not lighted on that night. Before the Committee met on Tuesday, however, they received a letter from the Brush Company, stating that they had been unable to carry out the experiment on the night in question, owing to the failure of the steam engine, and requesting that the Committee would allow the experiment to be made on the following night. The Committee, however, declined to accede to the request, and resolved that the Brush Company should be informed that they could not allow the experiment to be made on any night, unless they had received a week's notice of the intention to make it. The Committee also resolved that the Company should be informed that they could not allow the experiment to be made on any night, unless they had received a week's notice of the intention to make it.

Daily News (London) Sept. 6, 82.

ELECTRIC LIGHTING IN NEW YORK.

(BY ANGLO-AMERICAN TELEGRAPH.)

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, TUESDAY.

The first experiment of lighting sections of the city with Edison's incandescent electric lamps was successfully accomplished last night. Edison has laid eighteen miles of wire in pipes, and had placed seventeen thousand lamps in stores and offices. The work has been completed in about a third of this section, and about 6,000 lamps along six miles of wire were burning last night; the circuit including the Times and Herald buildings and some large offices. In all of these places the lamps were perfectly steady, and seemed more evenly distributed than from gas burners, while it gave out only a fifteenth of the heat of gas. The expense will be less than this, the lamps consume have a porcelain shade over an air-tight cone-shaped ground-glass globe four inches in diameter, in which is a carbon horse-shoe. All the lamps are on a multiple arc circuit, with the experiment light half-a-mile from the supply station. Where the work in the section is completed 20,000 lamps will be supplied from one station.

THE LIGHT OF THE FUTURE.

PROGRESS IN THE USE OF ELECTRICITY AS AN ILLUMINANT.

THE LIGHT.

The marvellous progress that has been made in this country within the past three years in the development of the electric light for ecclesiastical purposes renders it indispensable that the assessment of gas as the steady illuminator is rapidly ending, and that the electric will, as its partisans have persistently claimed, take out be the light of the future. Those who have any doubts on this score have but to make inquiries at the offices of the different electric light companies in this city, where hundreds of orders have already been filled and where thousands of applications for the new light from cities, towns and villages throughout the Union have been received; note the immense capital that has been subscribed to carry into effect their schemes, and examine for themselves the intricate but simple apparatus which is so rapidly revolutionizing the whole system of lighting, and which already bids fair to make the holders of gas stocks tremble with apprehension.

Of the several great electric light companies organized in the United States during the period referred to, six have established their headquarters in this city. In addition to these, several local companies—branches from the parent stem—are located here, and before the close of the year, from the orders that each have received and the extensive preparations that have been made, it is not at all unlikely that not only the metropolis but all the principal cities of the Union will be illuminated by the electric light. One company already has made satisfactory experiments in town, another will commence operations in a few days, and the remaining six have in some part of the island of Manhattan, or of Allerton will, in a few days, take decisive step; it is conjectured, favorable action on the report of the committee, recommending the passage of an ordinance granting the use by the municipality of the electric light as a means of illumination, and under which any company authorized by any law of this State can carry on its operations.

While the several electric light companies conduct their operations by different methods, they in reality are governed by two systems only—the Voltaic are system, named in honor of the inventor of the battery with which it was produced for the first time, and the incandescent system. These differ merely as to the means employed, the current being generated in the same way for both. The Voltaic are system requires that a number of pencils of carbon placed end to end are in the same circuit for so exacting their incandescence as to keep the ends of the two pencils stubbly separated from each other. The current of electricity is then made to pass through these ends, they are at first placed in contact with each other, and as soon as the current begins to pass are slightly separated, and what is known as the Voltaic are is formed between the ends of the pencils as the current leaping across from one to the other. This is intensely bright, and is the most powerful source of artificial light known.

The incandescent system consists of a continuous strip, made of material which is a not conductor of electricity, placed in a glass globe from which the air has been exhausted, and which, when the current is passed through it, is rendered so white heat, technically known as "incandescence," and so produces light. Carbon is now employed almost entirely for the incandescent part of each lamp, and as it would quickly consume in the open air it is enclosed in a clear globe in a vacuum or some gas which does not unite with carbon. The light produced by the Voltaic are lamp is very brilliant but of a blush tinge, and always more or less unsteady on account of the impurities of the carbon points and the difficulty of always precisely regulating their movements. In this form of lamp the pencils are gradually consumed, and the regulating machinery feeds them together to keep the proper separation of the points, but has not yet been sufficiently perfectly as to avoid considerable disfigurement of the light. The light produced in the way is much cheaper than any other artificial illuminator, and is especially adapted to places where the quality of the light is not so much of an object as quantity. The Voltaic system is largely used for lighting railroad buildings, large halls, exhibition, factories, warehouses, but is not adapted to lighting ordinary rooms, both on account of its objectionable adequateness and the great difficulty of subdividing it into small lights. The incandescent system, or electric attention, as the carbon pencils have to be renewed at least once a day.

The incandescent light is by far the most perfect artificial light yet devised, and is entirely free from all the objectionable qualities of the Voltaic are light, but is somewhat more expensive, although recent experiments have demonstrated that it is considerably cheaper than gas. In lamps of this form the currents can be subdivided to any extent and can be used in rooms of ordinary dwellings as gas is now used, the intensity of the same being easily controlled in regard to color. It is safe and requires no attention whatever.

The six electric light companies in this city, together with their branches, have a total capital of between $2,000,000 and $3,000,000. The rivalry between them for supremacy is extraordinary, each, of course, claiming to be the first in the field, the owners of letters patent of all the good points claimed by the other and of possessing the simplest, surest and best modes of all lights produced by machines of electricity. One or more are contesting almost every point on this score in the courts, but notwithstanding these trivial drawbacks all are making rapid progress, and are meeting more orders than they can fill for weeks to come.

The system of the Brush Electric Light Company is the Voltaic are system. The company occupies the entire building at 127 to 131 Broad, in connection with which it has a repair shop, a vibrant accretion, one of the most successful. It was organized under the laws of the State of New York June 10, 1878, with a capital of $1,000,000. The principal office of the company is in Cleveland, Ohio. Its officers are: President, Charles B. Pitzi; Vice-Presidents, Marcellus Hartley and Anson Phelps Stokes; General Manager, S. D. Schuyler; Secretary, L. E. Curtis; Treasurer, G. H. Williamson; Trustees, Charles B. Pitzi, Louis Fitzgerald, D. Willis James, D. O. Mills, Marcellus Hartley, Robert H. Mansfield, Henry B. Hyde, D. H. Haich, G. H. Williamson, Anson Phelps Stokes, Moses Taylor, Thomas H. Hubbard and L. E. Curtis; Consulting Engineer, Professor Elihu Thomson; Mechanical and Electrical Engineer, Charles F. Clarke. Of the different companies established in Boston, Lowell and Lynn, this is the only one which works both the Voltaic are and the incandescent systems. From the time the company's operations up to the present date it has made the Voltaic a specialty and has recently added the incandescent to its business with marked success. The vaults of the Mercantile Safe Deposit Company, the banking offices of Fisk & Hatch, on Nassau street, and the banking office of Hatch & Foote, on Wall street, are now lighted with the incandescent lamps furnished by this company. The current of electricity that supplies these lights are generated by dynamo-electric machines located in the basement of the Equitable Building. The company is now actively engaged in introducing the light in the city with orders for many residences, factory and business houses. The system is fully described in the city with letters of this description, and the company has in connection with its business facilities the avoidance of orders which have been pouring in, and has recently purchased a factory and machine shop, direct fire spaces and six stories in height at the corner of Avenue D and Seventeenth street, which it is now fitting up. Among the firms using the Voltaic lamps as proposed by the United States Company are the following: American Exchange Bank Chatham Bank, Equitable Life Assurance Society, First National Bank, Mercantile Trust, Company, D. O. Mills, New York Central and Hudson River Railroad Company's depots, Mercantile Safe Deposit Company, Mail and Express Building, Equitable Building, Mechanics' and Traders' Exchange, Produce Exchange, Cotton Exchange, Coffee Exchange, Consolidated Stock and Petroleum Exchange, Mutual Union Hotel, Saratoga; Central Line of Steamboats, Brooklyn, Co.; Harrison, Havemeyer & Co.; and John Wanamaker, Philadelphia; Forest Fibre Company, Berlin Falls, N. H.; New York and Paterson's Hosiery Company; Pennsylvania Coal Company; Scranton, Pa.; Pennsylvania Railroad Company, West Philadelphia; United States Torpedo Station, Newport, R. I.; Warner Brush Co.; Masury and Wonderful Inventions, in which electricity is the motive power, and which are also in use for extended description of the system, which is a well known, would be superfluous. The thousands of orders in this country and in Europe, however, who have been waiting patiently these many months in view of the successful completion of the incandescent systems, will be gratified to learn that he has overcome all obstacles, and that by the time before the close of the year will be not duty to all the principal cities of the world. The application of the Edison Electric Light Company for exclusion to use certain streets for wires to supply public and private buildings with the Edison lamps is now before the Board of Aldermen, and there is no doubt but that it will be granted. The company is already not yet known to the general hosiery by Wall Street and Gerome streets and the East River, and eventually will extend the system throughout the city. Application for the Edison light from any parts of the country and abroad have been pouring in in such a volume that it will be impossible to fill them for many months to come. The requirements of the great centres may be shown when it is stated that a separate committee has been formed for lighting railway trains, steamships, factories, factories and manufactories, and have their own electrical engineers. The Edison Electric Light Company of Europe, with offices in London, Paris, Berlin and Vienna, has been formed for lighting all Europe with the Edison Electric Light Company, of Europe, with offices in London, Paris, Berlin and Vienna. The officers of the Edison Electric Light Company are: President, Vice-President; R. L. Cutting, Jr., Treasurer, and E. H. Johnson, Secretary. The Board of Directors is composed of the following gentlemen: Edward H. Johnson, of the firm of the State of New York; Grosvenor P. Lowrey, of Lowrey, Kerr & Co.; Edison, Novelty Group, 21 to 25 Union Square; Edison Electric Light Company, 65 Fifth avenue; Edison Electric Light Company, 65 Fifth avenue; Edison Electric Light Company, 65 Fifth avenue

New Zealand Times, May 20th, 1888.

about three-sixths of an inch of the length of the carbon, and then flows off. The result is efficient by a pinch cylinder, which is sealed and fitted with screw caps. The full power of steam is thrown on the engine at first, and the power can be maintained per horse-power. The invention is the result of many years' ingenuity and ingenuity in its construction. The purpose of the Eastern Electric Manufacturing Company is to supply the electric light to towns and railway stations, but while retaining the right of manufacturers to grant exclusive licenses in certain districts. Mr. Hayes, Mr. Hayes, Washington, and others, associates have been organized to work on the plan. All the parts and accessories are made by machinery to advance interest the cost of manufacture. The Eastern Company was manufactured by the Eastern Electric Company, and when the right of manufacture is obtained the Company intends to supply the lamps at so much per lamp, in addition to the license fee. Any company desiring to manufacture, to be used in the Eastern States, can obtain the outside contracts by application to the Company.

The office of the Eastern Electric Manufacturing Company is at No. 113 Broadway. Its factory is at No. 37 Fulton street. The officers of the company are: President, Mr. Hayes, Washington; Secretary, John Hayes, Washington; Secretary, C. Sawyer, Electrician, W. E. Sawyer.

THE CENTRAL ELECTRIC LIGHTING COMPANY.

The seventh company on the list, The Central Electric Lighting Company, is also a new one, having widely in its methods from all others, gives promise of becoming popular and is doing an immense business. The company has been incorporated for the manufacture, construction, and operation of New York. New Jersey, Connecticut, Pennsylvania, Trenton, and Philadelphia, and the President Latimer, for saving in restrictions and conditions of the Company's charter. The system of Automatic lamps as operated by this firm any season be halted or extinguished at will.

The Company's system is known as the Constant Current Automatic Regulator, and Pendant Burner. The Automatic the gas is turned on and off automatically, and the current may or may not be used. The Pendant Burner is a simple burner set in a handsome fixture. The connection with Automatics, or Regulators, or them, the Pendant burners are applied. A light is produced by the passage of the current through a carbon with the gas fixtures, hangs from each burner. By pulling the cone the gas is turned on and off, and the second pull turns off and so continues indefinitely.

Three inventions have been introduced with marked success in Boston and other New England cities by the Central Electric Company. The exhibition of the system at the Mechanics' Fair in Boston and at the Academy and the National office and warerooms at No. 97 Union Square.

Danbury News (Ct) Dec. 19, 88

Edison Electric Light Co., of Danbury.

At a meeting of the subscribers to the stock of the above company held Friday evening the following persons were elected directors:

John H. Nichols, E. S. Davis, T. A. Mallory, D. H. Rogers, S. C. Hoisy, Benjamin Lynes, H. C. Lynes, A. T. Chase, Wm. H. Rider, J. E. Weed, F. S. Hastings (treasurer E. E. L. Co.).

These directors proceeded to elect the following officers:

S. C. LYNES, president; L. P. Trendwell, treasurer; Wm. E. Mallory, secretary.

Mr. Hastings explained the working of the system, and where plants similar to the one proposed to be placed here are proving financially successful. It is now expected that the remaining shares of stock will be taken, and the work immediately commenced and pushed to completion as rapidly as possible, and we may expect to see our stores, dwellings and other buildings lighted by the improved light within a short time. This shows the enterprise of our citizens, as Danbury will be the first place in this section, or in the State to be lighted by the electric incandescent system.

THE ELECTRIC LIGHT IN WELLINGTON.

Until a few days ago very few people in Wellington knew that the electric light was being introduced among them, and that the Parliamentary Buildings were not to be the only ones lighted by means of this new and important invention, and it did not transpire that the Queens had been completed to enable the Government Printing Office with light from the same source as the Houses of Parliament. The whole machinery was actually in hand. Two days ago the first work was commenced by Mr. E. Hayes, to whom the task had been entrusted, and right merry was the thing we in were to make a trial. Mr Willis J. Snow, the engineer representative of the Edison light, who had been chosen in preference to all others, was present throughout, giving directions with regard to detail, and especially with regard to the erection of the dynamo machine. A new building, measuring 30ft by 20ft, has been erected for the purpose, the engine and dynamo outside, and from here light and darkness is to be controlled. To begin at the beginning, it must be stated that the motive power is obtained by means of a portable steam engine of ten-horse power, made by Marshall and Co., and very handsome power is, however, required to secure the necessary velocity of the dynamo machine. The engine has been thoroughly secured, the wheels being fixed by struts which have been strapped and bolted in such a fashion as to reduce oscillation to a minimum. To fully describe the dynamo machine would be simply a repetition of what has already appeared in print with regard to the Edison inventions. The following brief notice will, however, convey a fair idea of its construction. The layman simply sees two plates about 4ft 6in high and 8in in diameter, which stand not less than a foot apart and are connected on the top by a heavy piece of wrought iron. They apparently left at the bottom, there being cut here to admit of the insertion of a bobbin measuring some twelve inches in diameter and about two feet in length. The bobbin knows that the ends of the wire are the two poles of a powerful electro magnet—not a magnet of soft iron as those which we generally wear, but a core of soft iron wound with fine wire. The bobbin is the armature of the magnet, and it is by the rapid rotation of the bobbin between the poles of the magnet that electricity is generated. In other words, it is by the rapid cutting of the lines of magnetic force, between the two poles. Two magnets are used, the two poles of the lamps. A particularly neat ingenious contrivance by which the armature is kept in the correct one to a hundredth part of a thousandth of an inch, according to the number of lamps which it is desired to burn, is in connection with the field magnets. By throwing in more or less coil magnetism of the field can be increased or reduced at will, according to the number of lamps to be lighted, and the expenditure of steam power can be regulated accordingly. The value of this important saving can thus be clearly becomes self-evident. The bobbin makes about 1,000 revolutions per minute when running at full speed, additional velocity being gained by means of a thunderbolt wheel. The wires leading from the dynamo are two No. 16, and are thoroughly insulated and kept apart a distance of two inches, the main branches which lead direct to the lamps being also allowed to come closer. Wherever a branch has been taken off special provision has been made for safety against the accidental insertion of a loaden plug. Should the current prove too strong for a branch this plug simply melts away, thus disconnecting the branch without interfering with any other part of the work. The total number of lamps at present put up in the building is 58, but this will be increased to 65. At present they are suspended by the wires which feed them, but these are to be put on proper fixtures. Each is of 16-candle power, and one of them serves the purpose of an ordinary gas jet, giving a far better and steadier light. Portable shades have been fixed over all of them, in order to throw the reading on the tables or below. We may say that the filament used is the small globes is an obtained bamboo, only the finest portions being shaved off for this purpose just under the glass of the cam. What the steam was first turned on by the present was less than 200lbs, and each lamp simply gave a red glow; but as the pressure increased the gradually turned into a brilliant white light, by which the gas appeared to be exceedingly dim. One or two stoppages had to be made, but they were entirely owing to adjustments which were required by the engine, and not by any portion of the dynamo wire or lamps. Henry lamp burst with the greatest bell fancy, and the works fully justified the explanations of Mr Snow and Mr. J. R. Hayes. We understand that the public will have an opportunity of inspecting the office while it is lighted up under the new and certainly superior system.

THE DOOM OF GAS.

What Edison Has Accomplished to Perfect Electricity.

New York City Soon to be Generally Illuminated by Electric Light.

Millions of Sewing Machines to be Run For Five Cents a Day Per Machine.

Interesting Interview with the Great Inventor About His Plans and the Future.

How He Has Worked Twenty Hours Out of Twenty-four to Master Every Detail and Overcome Every Difficulty.

About One Thousand Millions of Dollars Invested in Gas Stocks, and Their Enormous Profits.

In New York the Profits Amount to $6,000,000 Per Year—N. Y. Gets 15 Cents Per 1000—

$50 Shares held in $818—How Edison Looks and Talks—What He Proposes to Do for St. Louis and Memphis.

Special Correspondence of the Post-Dispatch.

New York, April 27, 1882.—Is the electric light cheaper than gas? Can it supplant gas as a cheaper means of general illumination? These are questions which the public, judging from the great advance in gas stocks, have generally answered in the negative, and not a few have declared that the electric light was therefore a failure. But Mr. Edison, in the interview which follows, declares that he will dispose successfully with gas for one-fifth to one-tenth the cost, and that the electric light is not of necessity, and he says his experience in New Orleans, Memphis and St. Louis [illegible] up between Spruce street [illegible] Nassau [illegible] Wall and the East River, will abandon gas entirely, &c., &c. [illegible] quite ill at the Everett House for a couple of weeks, but yesterday was well enough to sit up in an easy chair and to chat on the subject of the interesting battle between the electric light and gas. [illegible] wonderful amount of [illegible] there is in his man, who knows not what it is to have dyspepsia, though he already [illegible] eyes says he has an heart because he pulls out the hair roots of his [illegible] and is always saying away at the eyebrows, and whose eyes are so continually changing in color that one man says they are hazel-brown, the other blue, the other gray, while he himself declares he doesn't know what color they are; "Sea green!" declares Dod [illegible] inquisitor, after noting their rapid change from dark blue to a light gray on a greenish hue, and Mr. Edison, while [illegible] connected. With his smooth, thin, wan face, sharp, decided, strong features and [illegible] hair, prematurely tinged with slight streaks of gray, Edison makes upon one the impression of a man who has put seventy years' work into the thirty-five which he has lived, and yet there is a quickness and lightness about his manner which is almost juvenile, and his utter beardlessness make him look [illegible] "sentenced gray of his hair" is covered by his [illegible] soft felt hat. Mr. Edison comes of old Dutch stock on the one side—he remembers hearing his grandfather talk Dutch—and of Scotch on the other. One of his colonial traits, beside his pie-eating, is that he can be never [illegible] can reflect in bed; he always thinks out his most ferocious mathematical problems [illegible] around him. The first question asked Mr. Edison was whether it was true that Mr. Vanderbilt had his Electric lights taken out of his new house because they did not work well and because they had not [illegible] the woodwork, &c., some of the gas people had stated.

THE LIGHTS IN VANDERBILT'S HOUSE.

"It is false," Mr. Edison replied, smiling together his open vest. "We never tried one light. We have wired his house for lights from our station, in the way of general electrical [illegible] but though he would rather not wait till we came along there, and preferred to have an isolated plant himself. The first night on which the engine ran it made a noise, and I sent some engineer with, and Mrs. Vanderbilt complained of it, and that settled it."

"How about the alleged setting fire to the woodwork?"

"There is nothing in it except just this: In running temporary wires in different directions [illegible] to move Mr. Vanderbilt's effects, one of them came in contact with a burglar-alarm wire, and this one, being overheated, charred some of the gold-thread wires of the cloth wall-paper which it ran [illegible] it all."

The questioner now turned to the main purpose of the interview, the cheapness of the electric light.

"You have answer to that question in that we are going to sell the light as cheaply as gas," Mr. Edison replied. "[illegible] are 16,000 gas lots in the first district which we shall commence lighting up within a couple of months, and we have arranged to light all these 16,000 lamps, [illegible] at 25 per cent. We have got written agreements with ninety-three per cent of the gas consumers in this district that they will take the light, provided we furnish it at a price which we think we can [illegible]."

"Did you soon identify the [illegible] Edison whole to decide what these lots were?"

"Why, we soon identified them. [illegible] We have taken copies of them all; we have got the [illegible] consumers down. [illegible] We have got the [illegible] of each one. What will be your investment per 1,000 feet of gas in the seventy-three square miles of [illegible] district?" asked the reporter, [illegible] [illegible] [illegible]

The Electric Light.

It is the opinion of most citizens that the electric light is coming. It have an idea that it will be here before long. In talking about electric lighting they generally simply mention it, one will say another has put in the electric light plant, pushed it very much in their minds; there is only one that at once on its adoption renders its use of gas entirely unnecessary. That is the Edison light.

It can be placed in a store, house, etc., makes a magnificent indoor light, soft, white and steady. It does not flit, flare, the flaming noise, nor the fluctuations of the Brush light. It is of uniform brilliancy—it candle power—and it can be measured with absolute accuracy. In the distribution of territory among the various Edison light companies, Michigan fell to the New York company. That company has agents now in Detroit, who have already begun work. Hillsdale and Ypsilanti, I hear, have formed companies and will at once proceed to put in the Edison light. I understand that to five Michigan cities extra inducements will be offered, and after that the terms will not be so reasonable. Adrian may be one of the fortunate five. There is much to use in changing the light unless the change is made entire. The Brush and several other electric lights, furnish the illumination for large spaces, but are totally unfitted for use in houses, offices, etc. If either of these systems should be adopted by the city for street lighting, the gas company would be compelled to charge prices commensurate with more than they do at present, in order to make their business at all profitable. But an Edison light is suitable for streets, houses, offices, shops; anywhere and everywhere that gas is used, and in many places where the use of gas is impossible the electric light can be used with safety. There is no danger of accident from the Edison electric light wire, and the light, with all its manifold advantages, can be furnished the consumer at cheaper than gas. In city lighting the lamps are all connected, and are turned on and shut off simultaneously all over the city, by turning a switch at the central station. The advantage of being able to turn on all the lights in the streets, in an instant, would be appreciated some of the dark evenings when the moon is advertised to shine, but fails to do so.

THE EDISON ELECTRIC LIGHT.

(Special Dispatch to The Sentinel.)

CHICAGO, April 9.—A successful private exhibition of the Edison incandescent light, just introduced into Harrity's Theater, was given this afternoon under the direction of F. R. Pelouze, engineer for the Western Edison Light Company, Gen. Eastman Stager, president of the Western Telephone Company, H. H. Zabriskie, general manager of the Wisconsin Edison Company, and representatives of the druggists and newspapers. Many other prominent citizens and the gentlemen families with electrical tastes were invited. The invited guests were particularly pleased with the electric light, for it is reasonably free from the intense glare from the latter was clear, and the effect of twilight on the skies and in the vestibule and auditorium was charming. The motive power is supplied by one Lawrence engine of seventy horse power, and the current of electricity is made by two "Z" dynamo machines, giving 450 lights each, and one "Z" dynamo, giving 225. Of the former, one is used to supply the lights for the stage, the other for the halls and vestibule. The total number of lights in the theater is 677. In the basement are accumulators boxes, which are used to regulate the candle power of the separate circuits and give the engineer control over the

MOTIVE SYSTEM OF LIGHTS

used, enabling him to maintain the normal candle power. The flow of wire runs from the dynamo through the switch point under the floor, thence being carried to the boxes in the basement. From the boxes it is carried to the various lights. In connection with the switch board is an indicator which shows at once the power at which the lamps are running. An ingenious appliance is used to shut off the engineer instantly whether or not the lights upon the stage are turned on or off. Should the lights be turned on, the bell and two lamps, one red and the other blue, are set in motion. Should one or more carbons give out, the red lamp is brought into circuit automatically and the bell rung vigorously; should the engineer shut the current from the stage the blue lamp is brought into circuit and the bell rung vigorously. Should the switch be thrown off entirely, the bell and both lamps are set in motion. The lamps are placed in the border lights on the stage, and are arranged in rigging next in the same manner as the lamps are placed in the auditorium. The lights are of very small compass when scarcely larger than a cherry. They do not need to be shaded, but are rolled in paper as well, so that they are invisible to the audience. The lights in the border lights are of 100 candle power, and those placed in the same position as those in the parquet and gallery, and the remaining

SPECIAL FEATURE

of the system is the perfect safety from fire. Edison's system of electric conductors, which, from centre to centre, is only two inches apart, and every part of it is covered with a non-conducting material, which is impervious to the action of water, and which, if lighted, is calculated at the engineer's station, all within a room of fire-proof construction. Should a fire break out anywhere, everything is within easy reach of the engineer, and can be controlled at once. The entire system is complete and perfect in every detail. The current can be measured with absolute accuracy. The light is the result of the incandescence of a carbon filament in a vacuum, and the light is therefore free from the injurious effects of combustion. The steadiness of the light is another feature of the system. The steadiness of the light is the result of the perfect regulation of the apparatus, all the lights in the house being controlled by one switch. While the light is the finest and purest, it is also the cheapest, as it is the most economical

[Continued from first page.]

dry is especially important, as by this means the company not only receives its castings more promptly than heretofore, but also secures a better and purer quality of metal, a factor of prime importance in electrical work. On the ground floor of the main building are finely fitted and appointed offices, shipping-room, scales, driveway and everything pertaining to the forwarding department, all under cover, the driveway being between the shipping-room and offices.

The second floor is occupied wholly by the experimental work department, where all the new devices and appliances are first modelled, tested and perfected before being turned out in quantity. On this floor is a "K" dynamo, which furnishes light for the factory at night, attached to the main shaft by means of a friction clutch pulley. The dynamo is controlled by means of an automatic regulator, which keeps all the lights at a uniform candle power, whether there happens to be in use the whole number—two hundred and fifty—or only one light. If there are more or less lights in use, an arm in the regulator passes back and forth over a commutator, which throws in or lets out resistance.

Ascending one flight we reach the third floor where are made the safety cut-outs, plug, sockets and switches. The latest and most improved kind of machinery is used throughout, so that a large proportion of the work can be done by boys and therefore very cheaply, as to cost, the quality of stock used being of the best. On this floor, likewise, all appliances, whether plugs, cut-outs, sockets, switches, electoliers or brackets, are thoroughly tested, singly, before leaving the building. The distinguishing feature of the Edison system is the safety catch, as by means of the instantaneous operation of the same, absolute safety from fire is secured.

On the fourth floor, as also on parts of the third and fifth, are made the electoliers and brackets. Passing upward to the fifth floor we find that here are manufactured, principally, meters and regulators.

We would call special attention to the meter, which, like the safety catch, is used only by the Edison system; by means of this device the amount of light used by the consumer is accurately measured, and bills are rendered in accordance with the quantity of the same. All other systems charge a fixed price, no matter what quantity of electricity, more or less, may be used. The show room, a space of 100x20 feet, occupies half of the fifth floor, and is so arranged that any fixture may be lighted up at will.

Contained in this room are many rich and unique designs of electoliers and brackets, of Bergmann & Co.'s own manufacture as well as handsome devices of fixtures imported by them especially for the Edison light. Comprised in this list are beautiful hanging baskets, bouquets and bunches of flowers perfectly counterfeited in hammered and beaten brass, in which the graceful bells of light are enclosed in vari-colored cut-glass flowers. Here we find every possible and desirable appliance for office, store, desk, steamboat, railway station, hall, theatre, billiard room, library, study, chamber, bureau, ladies' boudoir, dining-room and wintnut, for there is seemingly no end to the uses to which this favorite light can be put. The effect is pleasing in the extreme, and one instinctively thinks of Aladdin and his lamp when in this apartment, and wonders if the author of the "Arabian Nights" did not in imagination forecast a nineteenth century scene like this. Be this as it may, the effect of the soft, mellow, but brilliant and steady light on and in the innumerable shades, colors and devices embraced in these many electoliers and brackets is a continual revelation of what "civilized electricity" will do at man's instant bidding.

The distinguishing characteristic of the Edison lamp is that it may be placed in any position or angle, but it is generally used downward, as in that way no obstruction is afforded to the free passage of the light. The sixth floor of the factory is used as a laboratory. The help employed in this establishment is of the best skilled German type, bright, clean-cut, keen-eyed, thoughtful, intelligent men and boys, the style of work prosecuted by Bergmann & Co. requiring the best "brain" power obtainable. The impress of genius is everywhere, the utmost system and nicety prevails, and the feeling that "electricity educates" as well as illuminates obtains. Bergmann & Co. have issued, within the last sixteen months, four editions of their illustrated catalogue, the fourth, just out, containing more than 50 additional styles of fixtures and appliances, which is remarkable as showing the unprecedented progress of the Edison system of incandescent lighting. The accompanying cuts represent a few of the numerous styles of brackets and electoliers produced by this company. No. 900 is a cluster globe for display, suitable for use where a powerful light is desired either for indoor or outdoor lighting. This "cluster" is made with five, seven or nine lamps, and will be found a very acceptable substitute for the trying arc lights. No. 100 represents a sliding student-lamp, including key socket and holder, an excellent device for the desk or reading table. The three-light electrolier here shown, with its flower-shaped shades, is a particularly beautiful fixture. The four-light electrolier on is less elaborately gotten up, but is decidedly handsome. The uses to which the light wall bracket may be put will readily suggest themselves.

ELECTRIC LIGHT AND ELECTRICITY.

Some Electric Stories from Personal Observation and Experiment.

Many Who Have Known Edison Since Boyhood Speak of Him as a Genius.

Some Interesting Facts in Favor of the Electric Light Company and Electric Lighting. Some Cities That Use the Light and Others That Are Going to Use It.

During the past few days we have had an installment of the proposed introduction of the electric light in this city; there has arisen a fitful fervor in the reopening months of the electric light and gas light when applied to similar uses of the old style. The electric light light mist have pulled against the gas light, especially against the Edison system, and repeat the words of Edison; that while we have the electric light, nothing more can be invented or required. The gas men admit that Edison has evidently enhanced his inventive genius; and assert that for practical purposes and every day use it falls far short of gas light.

If I see that an effort is being made to organize a new "electric light company," remarked a JOURNAL representative to Mr. Adams, that I have a dozen consumers in our papers that such was the case, and to talk about it." And shortly

"Have you any fears of such an opposition?"

"Not whatever. We may, should a company be established, lose for a time consumers, but the people of other towns say that an increased desire for gas."

"Have you taken the trouble to keep yourself posted on the merits and progress of the electric light?"

"I should certainly be a very poor President of gas company did I not watch closely all progress in the line of light, be it electric, gas or oil."

"Do I understand you, then, as following quite closely all your knowledge of electric lighting?"

"I feel quite sure that I am posted on its workings and in the progress," said Mr. Adams.

"What, then, do you think about its paying here?"

"Why, certainly our city can be no exception to other places. Not one cent of dividend has been paid. What lighting it does is for advertisement to sell the plants. The gentlemen are not even attempting the claim of economy, for only comes to sell the plant. So time goes for another city or village to attempte the same. A man capable of conducting and of successfully carrying on such a company, especially in a place like Saco, enough, must have a gentlemanly appearance, be easy of access, conversing, must be gifted and able to talk well on the topics—like in this case, where he comes there and tells of the wonders it has done elsewhere and that it can be done here for $3 to 40 per cent. he sure. People are tempted at such tempting bait. They do not stop to consider if there was any such profit there would be plenty of men anxious to dispose of it would dover let it slip through their fingers," said Mr. Adams, emphatically, "if the real facts and figures were known. I have received these with ease in case, [illegible]

[illegible] circular speaks of [illegible] which [illegible] but it is necessary to [illegible] what he means by economical. I do not want to hear from all the [illegible] have made the attempt. Where I [illegible] statement is absolutely false in some cases, I say I may be in error, but I do not hope in all."

In what particular have you found the gentlemen's statements incorrect?"

"Well, for instance, in the one [illegible] talking from his pocket's package of [illegible] he says his principal is the Watertown, in this State, after naming many prominent cities and towns where they are using it, that it is run very satisfactorily. Now, what is the truth? The light is not there at all. It was there but a short time and they took out the machine and wires and left. Again, at Williamsport, Penn., one would infer from reading this circular, that the town was alive with electric lights. What is the fact? Only six business places took it, and one has already given it up, and another is on the fence. So, also, after persistent canvassing the system is about done, for, in fact, only [illegible] Again, at Oswego, N. Y., it says all places the electric light should properly have. Mayor Farley telegraphs that they will probably discontinue its use, as it costs them more than ever. At Auburn, where the ring did work through the people and brought the plant, the circular says that "for once the conservative people have gone too fast. Seven five times what gas does." Stocks and bonds are on the market continually, and [illegible] the market conditions. If I have so well, I will say it is a very amusing message of Mayor Manning, of Buffalo, but I am pleased to say, said, "That in refusing to sanction the introduction of electric lighting, I do so because gas can be had for 60 per cent. less." In a recent interview, Mr. Manning said he had promised to light up during the [illegible] New York in honor of the [illegible] of his stockholders, by the canvassing with this system. The statement: "If I [illegible] is an exceedingly profitable business, when done on a large scale," the public would be dissatisfied with the [illegible] prices we ask. On the other hand, if I say we can compete with gas and have to put in the electric light for about the same, then the investing public will not put its money in it." In fact [illegible] demonstrated," continued Mr. Adams, "the [illegible] and supporters that in all its [illegible] is too expensive and unreliable for general purposes, and that the business is one of speculation on the part of those who have patents and appurtenance to sell. The [illegible] being extended where longest in use. Four years ago the holders of gas stocks were frightened, as gas companies they made and stocks fell. Then came the rage. The report of the New York City Gas Commission says: 'The electric light is 70 cents a night—costs the city $400.00 a year. It displaces gas lamps which at $17.50 each cost the city $116.50.' Now we see that we cost on, and we have in one thing, and what is being done in another. The Boston Transcript says that there are two classes of companies in existence, one for gas and one for electric lighting, and the other is managed by men of means who offer no stock for sale but are charging off no profits. The Transcript says that the more they do the more they lose."

"Do you think the electric light will

CYNTHIANA DEMOCRAT.

CYNTHIANA, KY.

FRIDAY, OCTOBER 26, 1883.

THE ELECTRIC LIGHT

Shall Cynthiana Have It?

A COMPANY FORMED AND A LARGE PART OF THE STOCK ALREADY TAKEN.

The Old Town Waking Up—Get Steve (Electricity, Light.)

For several weeks the subject of forming a company to introduce in Cynthiana the Edison incandescent electric light has been agitated, and when we called Louisville we became satisfied it was no longer an experiment, and published a full description of the light, the manner of production, the cost, &c., &c.

On our solicitation Mr. A. Sweeny, of the Ohio Installation Company, a licensee of the Edison Company, came to Cynthiana on our occasion to work the matter up. A meeting was called on last Monday evening at the Council Chamber, which was attended by the principle business men of our town, such men as J. W. Peck, J. W. Hopkins, D. C. Givens, Luther Van Hook, John Montgomery, J. T. Hedges, Prof. Brown, L. W. Whaley, J. W. Smiser, Wm. Addams, W. L. Northcutt, T. W. Remaley, and many others. Mr. Addams was made Chairman of the meeting, and R. V. Bishop was on motion made Sec'y. Messrs Stuart and Story, of the Ohio Installation Company, explained the matter, and gave the terms on which they would install a plant in Cynthiana, and agreed to have the light burning by the middle of December if the company could be formed and the money subscribed in a reasonable time.

A subscription paper was started, which was promptly headed by T. J. Hopkins with $1,000. J. W. Peck then followed with $1,000. Wm. Addams, $1,000, L. VanHook $500, W. J. Kehoe $500, making $3,000 subscribed in a few minutes. Subscribers were also secured as follows: Prof. King $500, J. T. Hedges $500, Chas. Willson $200, making $5,000 in all.

On motion the chair appointed W. J. Kehoe, W. L. Northcut, J. W. Peck, Wm. Addams and J. W. Hopkins as a committee to solicit stock.

The subscription paper is now in our hands and will be circulated for everybody desiring to become a stockholder.

It is proposed to furnish the light to 16 lights per hour for each lamp of ten candle power. This would be equivalent to gas at about three dollars per thousand feet. Chris pays $2.50 for gas, and Mr. Hedges pays $4.50. The electric light, however, has so many advantages over gas that it is really worth $5 per cent. more. There is no cleaning, no soot, no dirt, no danger with the electric light, if there is never a fire caused from this Edison incandescent light, and the company has never had a plant rejected. In addition to furnishing light, power and heat, can be furnished at reasonable prices.

The following letter was received in reply to an inquiry as to the success of the Edison Illuminating Light Company of Sunbury, both financial and otherwise:

OFFICE OF EDISON ELECTRIC ILLUMINATING CO. OF SUNBURY, PA.
ATTORNEY-at-LAW.
SUNBURY, PA., Sept. 29, 1883.

W. J. Kehoe, Cynthiana, Ky.:

DEAR SIR—Yours at hand. You desire to know something of the profit in the Edison Electric Light Company. Our plant is a new thing here and we are obliged to combat the prejudices against other systems of electric light and also a local gas company. We have been quite successful. It is beyond all question the best system of lighting.

As to the profits of the company, it is rather early estimated. We have gone so far that we feel that we will be handsomely remunerated for our trouble. We estimate that 350 lights will pay all our expenses. We now have 500 lights in, with sufficient premises to put in all of our plant—5000 lights. We estimate a dividend of 25 per cent. I do not think we will fall far short of it.

Respectfully, FRANK S. MASS, Treas.

Later information from Sunbury indicates that the stock of the Electric Light company there is paying, handsomely and is worth a premium of $25 and none to be had at that. Similar favorable reports are heard from Shamokin.

The following letter, has been received from Shamokin in reply to an inquiry.

OFFICE OF W. H. DOUTY,
DRY GOODS MERCHANT, &c.
SHAMOKIN, PA., Sept. 27, 1883.

W. J. Kehoe, Esq., Cynthiana, Ky.:

DEAR SIR—Your favor 24th inst. received. In reply would say that we have just started our plant, which is the Edison, and cannot say in positive terms as to what we can do. As for the light, there is no doubt about it being the best in the world for general lighting. I am fully satisfied that we can run our plant with 240 lights and pay all expenses, labor, electricide, insurance, taxes, water, depreciation of 5 per cent., fuel, &c. Our plant is capable of 1000, that is what I term 1200 lights for dividend. We will sell the light, the electric power, for 1 cent per hour.

Yours truly, W. H. DOUTY, Pres't.

IT IS A THING OF BEAUTY.

A Reporter Interviews the People of Sunbury Who Are Using It—Hear Their Views.

[Williamsport (Pa.) Sun-Telegraph.]

Certificates of stock are or about to be issued to the members of the Edison Electric Light Company of Sunbury. This new enterprise is in a flourishing condition, and is crowded by everybody to be a thoroughly practical success—by which is meant, that the Sunbury Gas Company have, which has reduced the price of gas light $2 per 1000, on account of the formidable rivals upon its business by the new light, says through its heaviest stockholder that it will lose $1,000 this winter if competency to run out that Edison party. No doubt points look of the significance of the Electric light can be at less than the failure of dismay from the gas company. It is sufficient to say that the success of the electric light that it stands entirely on its own feet is on those points adopted by the people of Sunbury. It is a positive and cheaper light; that they ever had here; although the gas company's additional income, in the shape of their ill-concealed mortification and extravagant threats to rob it out, will be appreciated by the men who are directly interested in the new light. It seems to your correspondent, too, that the gas company's $1,000 would be but a drop in the bucket that, would be required to drown the new light. This A. Edison, of New York, the inventor of the light, and his millionaire New York coadjutors, hold a large amount of stock of the Sunbury company, and as Mr. Edison has some $5,000,000 backing him in his enterprise it is reasonable to suppose that he is to a position to hand from with refractory gas companies anywhere.

THURSDAY, SEPTEMBER 27, 1883.

ELECTRIC LIGHTS IN ORIDORPORT.—
A bright Sun burned clearly in the old-fashioned town hall, Oridorport, on one end of the Board of Trade's room in Wheeler's building, Wall st, 6 o'clock last night, about forty gentlemen assembled to see the magic illumination recently against the will of all other of its spectators. They represented the commercial Council, the Board of Trade, the Board of Education, and one "third ward old established manufacturing concerns, and had come in response to the invitation sent out to consider the subject of electric lighting by this city. After they had sat around and warmed their hands for a time and talked over the prospects of the fall trade, Major D. Read arose and called the meeting to order, and then everybody hastily availed themselves of the opportunity to nominate and elect their chairman. Mr. Henry Atwater, of the Bridgeport Malleable Iron Company, was chosen secretary. Mr. Read noted the fact that as President of the Board of Trade he had been peculiarly unsuited to introduce electric lighting here, but he had been led to the matter from various standpoints and given the fullest thorough consideration, and, as a private citizen, he had never "met the present time which satisfied that the mode of lighting possessed sufficient advantages to warrant its adoption." He had made a brief statement of the system, but they did not like the light. He was very desirous of using the light in his own house, and knew of others in the city who also desired it; but none of them would find it constantly "what" could be used conveniently. However, he continued, "two gentlemen now come forward and say that they have invented one or several with better and cheaper lights than we now have, and I believe that if they could do as they promised they would find plenty of our citizens to help them along." Mr. Read then stated that meantime he intended to think that our city was a little behind in progress, for in many places the electric light was in constant use. Most recent people had tried it and not made it work successful. It is true, but now we were assured that it can be made to pay and will be satisfactory. Continuing upon this theme, Major Read remarked, "We have the most extensive street lights in this city that I ever saw, and I, for one, advocate certainly and heartily the new system. Here and remain over night in the dark. I don't think we all might do all in our power to help it along." He then called upon Mr. H. F. Strong, who is familiar with the Brush system, to explain some points to the meeting. The gentleman remarked, at introduction, that he wished to be understood as only speaking in general terms, and not in favor of the Brush system especially. This system has, he said, four "A's," light, and principally [illegible] [illegible] [illegible]

FEBRUARY 10 1883.
THE GAZETTE, MONTREAL.

PROGRESS OF ELECTRIC LIGHTING.

Our readers, especially those who have to complain of excessively heavy gas bills, interested to learn the progress of the « Dia- lighting apparatus, suits were commenced against mond » Electric Light Company, which was both, parties—against Maxim in France, established by Edison in New York, where where a seizure of his lamps was made at the Electrical Exposition in Paris, and against Swan in England. Both suits are now down for hearing, and will probably be decided within a very short time.

"THE CRAIG ELECTRIC LIGHT."

TO THE EDITOR OF THE GAZETTE.

Sir,—On the 12th inst. the following statement appeared in the *Daily Star*, concerning "The Craig Electric Light;" of which an exhibition had been given the evening previous at the repair shops of the Grand Trunk Railway at Point St. Charles:

"The apparatus had been examined by the Chief Engineer of the Post Office Telegraphs of Great Britain, and a certificate given that it is the best yet invented; and Professor Morton, Principal of the Stevens Institute, Hoboken, although on the Advisory Board of Directors of the Brush Company, has certified that it is the only perfect system in the world."

Being interested in the development of electric lighting, I determined at once to forward the above statement to the gentlemen referred to, in order to ascertain its truthfulness or otherwise.

Mr. W. H. Preece, engineer and electrician in chief of the postal telegraphs, London, England, called me as follows:

—London, 19 April, 1883.

"I know nothing of Mr. Craig or his dynamo, and have not given any certificate to any one."

Wells Professor Henry Morton, of Hoboken, New Jersey, telegraphs my assistant, Mr. H. M. Byllesby (who was one of the professor's pupils), as follows:—

—Honesdale, 17 April, 1883.

"No such statement as you report was ever made by me."

The above disclaimers speak for themselves, and in the public interest I beg to ask the insertion of them in your journal.

Yours faithfully,

THOS SWINYARD.

Hamilton, Ont., 19th April, 1883.

OCTOBER 24 1882.
THE DAILY NEWS.

ELECTRIC LIGHTING.

TO THE EDITOR OF THE DAILY NEWS.

Sir,—I see by the papers that Edison claims that both the Swan and Maxim inventions are infringements of his patents, and, after obtaining the opinion of eminent counsel and scientific experts, both English and French, that they are unfounded

I have been asked to give a brief history of the matter, which I have given; considering it of some interest to the general public. Should you consider it worthy a place in your columns, I shall be pleased to have it inserted.

Edison's claim to the "subdivision of the electric light" is based upon the fact that under the head of preliminary estimate, he estimates a "plant" for lighting a district containing 1,000 lamps, with engine, boilers, dynamos, leads, &c., complete, at $130,000, or $130 per lamp; and that under the head of "preliminary estimate" based upon "subdivision," he estimates a plant for lighting the same district with 10,000 lamps, with engine, boilers, dynamos, leads, &c., complete, at $300,000, or $30 per lamp; and argues that the saving effected by the latter estimate is the result of his invention of subdivision. Now, this is absurd on the face of it, as the saving is effected entirely by the use of a larger plant, and not by subdivision at all. Edison's claim is based upon the assumption that a certain number of lamps can be run from a certain sized plant, and that by subdividing a larger plant into smaller ones, the same number of lamps can be run from the smaller plants. This is absurd, as the number of lamps that can be run from a plant depends entirely upon the capacity of the plant, and not upon the subdivision of the plant. Edison's claim to the subdivision of the electric light is therefore worthless.

Edison's claim to the invention of the carbon filament is also worthless, as Swan's patent, which was granted in 1860, and which is now in force, covers the use of carbon filaments in vacuo, and Edison's patent, which was granted in 1879, covers the use of carbon filaments in vacuo. Edison's claim to the invention of the high resistance lamp is also worthless, as Swan's patent, which was granted in 1860, covers the use of high resistance lamps, and Edison's patent, which was granted in 1879, covers the use of high resistance lamps. Edison's claim to the invention of the parallel system of distribution is also worthless, as Swan's patent, which was granted in 1860, covers the use of the parallel system of distribution, and Edison's patent, which was granted in 1879, covers the use of the parallel system of distribution. Edison's claim to the invention of the regulator is also worthless, as Swan's patent, which was granted in 1860, covers the use of a regulator, and Edison's patent, which was granted in 1879, covers the use of a regulator. Edison's claim to the invention of the automatic cut-out is also worthless, as Swan's patent, which was granted in 1860, covers the use of an automatic cut-out, and Edison's patent, which was granted in 1879, covers the use of an automatic cut-out. Edison's claim to the invention of the safety fuse is also worthless, as Swan's patent, which was granted in 1860, covers the use of a safety fuse, and Edison's patent, which was granted in 1879, covers the use of a safety fuse. Edison's claim to the invention of the electric meter is also worthless, as Swan's patent, which was granted in 1860, covers the use of an electric meter, and Edison's patent, which was granted in 1879, covers the use of an electric meter. Edison's claim to the invention of the electric motor is also worthless, as Swan's patent, which was granted in 1860, covers the use of an electric motor, and Edison's patent, which was granted in 1879, covers the use of an electric motor. Edison's claim to the invention of the electric light is also worthless, as Swan's patent, which was granted in 1860, covers the use of an electric light, and Edison's patent, which was granted in 1879, covers the use of an electric light. Edison's claim to the invention of the electric lighting system is also worthless, as Swan's patent, which was granted in 1860, covers the use of a lighting system, and Edison's patent, which was granted in 1879, covers the use of a lighting system. Edison's claim to the invention of the electric lighting apparatus is also worthless, as Swan's patent, which was granted in 1860, covers the use of lighting apparatus, and Edison's patent, which was granted in 1879, covers the use of lighting apparatus. Edison's claim to the invention of the electric lighting system is also worthless, as Swan's patent, which was granted in 1860, covers the use of a lighting system, and Edison's patent, which was granted in 1879, covers the use of a lighting system. Edison's claim to the invention of the electric lighting apparatus is also worthless, as Swan's patent, which was granted in 1860, covers the use of lighting apparatus, and Edison's patent, which was granted in 1879, covers the use of lighting apparatus.

AND BOSTON JOURNAL OF COMMERCE.

VOL. 21.—NO. 1. SATURDAY, OCTOBER 21, 1882. PRICE SIX CENTS.

THE EDISON SYSTEM OF ISOLATED LIGHTING.

When the writer of this was running the reportorial quill on a daily paper in New York city, some three years since, he was detailed more than once to visit the "Wizard of Menlo Park" and had pleasant interviews with him. He has also lived to see the abuse, which has been heaped upon Mr. Edison's head—by a set of know-nothing journalists, who, unless they are scientificists are nothing, and as scientificists are never reliable—turned into admiration of his merit and acknowledgment of his complete triumph.

The rapid stride made in electric lighting has been a matter of astonishment. It is safe to say that no man more than Thomas A. Edison has achieved success, or what is more gratifying to manufacturers, has achieved so signal a success that the electric light of to-day is free from the incidentals that have always attended gas and the accidentals that are to too close fellowship with kerosene oil. The Edison light is as far superior to any other light for manufacturing purposes as first-class kerosene is to moonlight. This is our own private experience. We have looked with much interest at the adoption of the electric light; we have seen it in the old world and the new; and it is only after some months of careful investigation with respect to its adoption by the manufacturing interests—and by manufacturing we mean everything as well as textile—that we are rather proud to say that the Edison light of to-day is the light, in its perfection for its advance of any and all others.

The Edison light is unlike any other electric light, and after Mr. Edison had thoroughly studied all that related to electric lighting, the circumstances under which it must be used, the purposes for which and the place in which, instead of pleading the invention of others, making up arrangements which should neither be one nor the other man's system or invention, he made a most radical departure from any one who had preceded him, and invented a system of lights and of the appliances which were necessary to make that system successful and capable of adoption. This, as a matter of course, required time. How successful he has been, only those who have been most closely connected with him during all this work, can say.

It is true that during the time that through the delays caused by lengthy experiments he has been heard by the press, but on those who laugh last laugh longest, so Mr. Edison can afford to forgive those people for their ignorance, from the fact that he now offers the only thoroughly practical isolated light, and the only light that is completely applicable to the manufacturing or mechanical establishments where a natural light, one that does not glare the eye, and one which in case more of a blindness than a help, is demanded; where a light has a natural and pleasing softness rather than the pale, ghastly white; where a light of small capacity, like eight or twenty-candle power, is furnished without that peculiar and almost intolerable flicker, jumping motion, or whatever term may be applied. While he has accomplished all this, he has also accomplished what was most important and essential requisite—that of proportioning his power to the lights required, so that one, three, or all the rooms of a large establishment can be lighted perfectly; and if all the lights are required it is only a matter of momentary attention to graduate the power of the engine to the work required; and if, on the other hand, only a portion of the work is required, it takes but a moment both to diminish the volume of the current and the work of the engine with a velocity that nothing approaches in comparison more completely than the microscope attachment of the telephone of a fine watch. These points will all be considered by the manufacturers.

Mr. Edison has also accomplished other and important changes which are set forth further on in this article. He has astonished closest scientists by his seeming contempt for positively acknowledged laws in relation to electricity; he has ignored old and adopted standards,—which indeed had to be set up sooner or later—he has adopted standards of his own, seeking out first by careful calculating and empirical experiments the basis or the foundation which he was to adopt. He has proved that he can accomplish more with the same number of power, and more times money; he has given us a better light, and he has magnificently accomplished the task which he set himself, without adopting the too prevalent practice of swindling either his patrons or those who have interested in a business manner with him.

We have sought in this article to avoid all theory, to make only statements of fact, and to give to be such as shall interest our readers who have a wish to acquire such authentic information in reference to this new child of invention, with a view to its adoption into their family. It is not a matter whether these families are large or small. Some of our manufacturing concerns have disseyled one to two thousand gas burners, and introduced seven to nine hundred Edison isolated lights, and we shall now show what those lights are doing by facts taken from the current expenses' sheets of those institutions. We are promised these facts and we shall very shortly give them publicity.

We have sought, in this article, to discard all biased statements of comparisons, and to confine ourselves simply dayly to fact, and we bespeak from our readers careful attention while figures are given. Those who have not, should by all means visit the New England Manufacturers and Mechanics' Institute, where the several systems are now to be seen; on each of the days of the week, in full operation, and where any man, with good average ability, can make his own comparisons and deductions, with perfect satisfaction to himself, from a basis of business, which is the only tangible or satisfactory one.

In the Edison system no arc lights are used, the originators of that system believing that for the same power expended at the engine, or wheel, small lights, *distributed* over a given space, would give a far more effective illuminant; for, by the Edison system (the sun) with open, shadowy must inevitably ensue. Edison uses what is known as an incandescent lamp, in which there are no moving parts and no mechanism; the light, therefore, is absolutely steady, provided the power is so. This lamp consists of a pear-shaped glass globe, about six inches in length. Within is the "carbon" about the size of a small ascending a horse hair, is made of bamboo fiber from which all volatile matter has been removed and is nearly pure carbon. This carbon is fastened to a small copper strip by holding the wire like a clamp about the enlarged ends, and the contact is rendered more perfect by electroplating. This in turn is attached to the platinum wire, a piece of platinum in fig. 2. These lamps are of no such length as those in the "carbon" system, but of no such length as those in the "leading in" wires. The platinum part is hermetically sealed in the end of a glass tube which also contains the copper wire. The reason of this is that the platinum's coefficient of expansion is almost exactly the same as that of glass, and consequently the two expand equally; therefore, the glass is not broken and the vacuum mentioned below is maintained. The base of the lamp is made of plaster of paris. At its bottom terminals of the lamp, and to which one of the "leading in" wires is soldered to a socket, which fits into the plaster into the form of a screw thread. This forms the other terminal. The air is now exhausted from the globe until a practically perfect vacuum is obtained. The light is produced by the current passing from the bottom plate contact screw, and base to the second plate. As the carbon is of very high resistance, the mechanical energy furnished by the engine or water wheel is transformed first into electrical energy, and then into the energy of heat. Below is given (fig. 1), a cut of the lamp. A represents the glass globe, B the carbon, C the plaster base, D one terminal, and E the other terminal. The average life of these is guaranteed to be at least 1000 hours, but they have proved immediately below the cut of the lamp, is represented the socket. O is a plate fitted to receive the plate, D. Below (out of sight in diagram) is a plate, T, connected from first, on which rests the plate, E. The socket is attached to lead ceiling (in factories and workshops) by means of a 1 inch pipe, which screws into the plate H. The top wire lead down inside of this pipe, one being attached to the plate, O, and the other by means of a small lead wire to plate, F. This lead wire serves as a safety guard; for since lead has about thirteen times the resistance of copper, if any short circuit or cross is accidentally produced, thus setting up an extra current, the lead will melt and the wire be broken, stopping the flow at once before the copper is heated. The key, K, enables us to break the circuit at pleasure, thus "extinguishing" the light. Each lamp is thus entirely independent of all others, and can be turned on or off at will. Fig. 2 shows the lamp in position in the socket, being secured in this line at the screw threads, D and O. The lamps can be used in a gas fixture, but in industrial work it is better to suspend it globe down, as by means of a metal or porcelain shade, attached to the socket and over the lamp, all the light is thrown down to the work in hand. This shade also serves as a protection to the lamp. If it is desired, however, to have a lamp whose position can readily changed, swinging brackets, with one, two, or three arms, are provided as a matter of fancy. These brackets can be attached to the wall or suspended from the ceiling, as mentioned above. At the circuit between the wire in which the current is to be made through brushes in the box A, and not by means of switches of wire, there is no danger of breaking this circuit by turning the arm B, which may be revolved indefinitely. At the junction of the top wires with the mains carrying the current from the generator, is interposed the "cailing cut out" or safety catch, represented by Fig. 4. This consists of two posts, the blocks, A and the plate, B. The main wires are led through the grooves, M, and the top wires through the grooves, T. At the base of the plug is a plate of copper, in which about the width of the plug is pressed, as in the base of the lamp, into the form of a screw. These are connected by means of a lead wire, C. When the plug is inserted into the block, A screws over O, and D upon P. The current enters at S, passes through the lead wire to O, thence up the top wires to lamp and back to main at X. This safety catch serves an analogous purpose to the automatic sprinkler in a factory. In the latter case, an abnormal heat melts the fusible metal, thus allowing the water to flow; in the safety catch, an increased current melts the lead wire, for the reason mentioned above, thus breaking the circuit. This current might otherwise dangerously heat the copper wires. This device is a distinctive and the noteworthy feature in the Edison system. As the means of a lead wire, C. When the plug is inserted into the block, A screws over O, and D upon P. The current enters at S, passes through the lead wire to O, thence up the top wires to lamp and back to main at X. This safety catch serves an analogous purpose to the automatic sprinkler in a factory. In the latter case, an abnormal heat melts the fusible metal, thus allowing the water to flow; in the safety catch, an increased current melts the lead wire, for the reason mentioned above, thus breaking the circuit. This current might otherwise dangerously heat the copper wires. This device is a distinctive and the noteworthy feature in the Edison system. As the power lamps. In each of these cuts A represents the arms of the electro magnets, B the pole pieces between which the armature, B, revolves, and K the keepers. The brushes, O, collect the current generated in the armature, B, from the commutator, T. The current passes from one brush along the conductors shown on side of magnet arms to the top of the machine where it divides, part passing off by conductor, C, to the feeder through the lamps back to D, and part passing about arms of magnet, joining the return current in the conductor C to the other brush. When the machine is first started there is no perceptible magnetism in the pole pieces

sented the socket. O is a plate fitted to receive plate, D. Below (out of sight in diagram) is a plate, T, connected from first, on which rests the plate, E. The socket is attached to lead ceiling (in factories and workshops) by means of a 1 inch pipe, which screws into the plate H. The top wire lead down inside of this pipe, one being attached to the plate, O, and the other by means of a small lead wire to plate, F. This lead wire serves as a safety guard; for since lead has about thirteen times the resistance of copper, if any short circuit or cross is accidentally produced, thus setting up an extra current, the lead will melt and the wire be broken, stopping the flow at once before the copper is heated. The key, K, enables us to break the circuit at pleasure, thus "extinguishing" the light. Each lamp is thus entirely independent of all others, and can be turned on or off at will. Fig. 2 shows the lamp in position in the socket, being secured in this line at the screw threads, D and O. The lamps can be used in a gas fixture, but in industrial work it is better to suspend it globe down, as by means of a metal or porcelain shade, attached to the socket and over the lamp, all the light is thrown down to the work in hand. This shade also serves as a protection to the lamp. If it is desired, however, to have a lamp whose position can readily changed, swinging brackets, with one, two, or three arms, are provided as a matter of fancy. These brackets can be attached to the wall or suspended from the ceiling, as mentioned above. At the circuit between the wire in which the current is to be made through brushes in the box A, and not by means of switches of wire, there is no danger of breaking this circuit by turning the arm B, which may be revolved indefinitely. At the junction of the top wires with the mains carrying the current from the generator, is interposed the "cailing cut out" or safety catch, represented by Fig. 4. This consists of two posts, the blocks, A and the plate, B. The main wires are led through the grooves, M, and the top wires through the grooves, T. At the base of the plug is a plate of copper, in which about the width of the plug is pressed, as in the base of the lamp, into the form of a screw. These are connected by

system is always installed by competent men, no short circuit can occur except by accident, in that event the safety catch is on the alert to provide an instantaneous and effectual remedy. In a factory or other shop building where it is desirable to have an arrangement whereby a number of lamps may be shut out simultaneously (as for instance, in the separate rooms or separate bays in the same room), without turning the keys in the individual lamps, a "switch" is inserted in the line at the generator, which is a central feeder coming from the generator. On a dark or cloudy day the globe nearest the windows not require the light as soon as those in the center of the room. The former can be shut off by the switch itself required, when the lamps are all turned on at once.

Where a large number of lights are distributed over several stories of a building, or where the light is required at some distance from the generator, the "electric tube" replaces the central feeders mentioned above. The tubes are the same as used by the Edison Illuminating Company of New York, in their "First District." These tubes consist of a series of gas piping in which are placed two small-gutticinal copper rods, separated from each other and from the containing pipe by means of incombustible washers; the interior of the pipe is filled in with dry sand, dried having run times the insulating properties of gutta percha. These tubes may be connected to a junction box at any point where it is desired to use the current. These junction boxes are constructed similar to the generators or governors. These machines are of three sizes, known as "Z," "K," and "Y." Fig. 5 is known as a "Z" machine, and is capable of producing a current sufficient to furnish from 45 to 65 lamps at 16-candle power, or 120 to 130 lamps at 8-candle power. This will perhaps be more readily comprehended when it is stated that 16 candles represent the light furnished by an ordinary argand burner consuming 5 to 6 feet coal gas per hour. Fig. 6 represents the "L" machine with a capacity of 150 to 180 16-candle power, or 300 to 320 8-candle power lamps.

Fig. 7 is the "K" machine, with a capacity of 250 16-candle power or 500 8-candle power lamps. In each of these cuts A represents the arms of the electro magnets, B the pole pieces between which the armature, B, revolves, and K the keepers. The brushes, O, collect the current generated in the armature, B, from the commutator, T. The current passes from one brush along the conductors shown on side of magnet arms to the top of the machine where it divides, part passing off by conductor, C, to the feeder through the lamps back to D, and part passing about arms of magnet, joining the return current in the conductor C to the other brush. When the machine is first started there is no *perceptible* magnetism in the pole pieces

There is present, however, what is known as "residual" magnetism. This is sufficient to induce a slight current in the armature, by what is known as "mutual accumulation," and this, a reciprocal action between the armature and pole pieces, this slight current is increased until the limit of magnetism in the pole pieces is reached. In practice, instead of connecting the main leading from brush directly to the magnet wire, it is customary to connect through the "resistance box." By means of these magnets depends in part upon the number of turns in the helix on the arm, and in part upon the strength of current passing, less current making the magnets weaker. As the magnets are connected in "shunt circuit" or "multiple arc" to the main circuit, resistance inserted in the magnet helix will weaken the current of electricity passing about the magnet. This is the object of the resistance box, which increases resistance but outside of the magnet arm. Thus the strength of the magnets, and consequently the power of the lamps, can be varied at will. As the magnets are shut off, or are "turned down," the resistance is cut out. These machines are particularly decreased and the life of the lamps is greatly increased—two very important items to be considered in the running expenses of the system. Regulators for the engines are also required which automatically adjust for a change in load. They are not positively required where the load is constant, as in cotton factories. The generators are connected to the engine are in the same manner, and therefore each machine can be shut out at will. At the exhibition made by the New England Manufacturers and Mechanics' Institute fair, the three sizes of dynamos, and also five different sizes of lamps, are so connected. The power is applied from the countershaft by means of a belt on P. The dimensions of these three machines are as follows:

Machine.	Length.	Width.	Weight.	Pulley.	Speed.
	Inches.	Inches.			
Z	30	20	2000	6x10	1200
L	40	30	3000	8x10	1200
K	48	36	4000	8x10	1200

Fig. 8 represents the "Edison-Sawyer Dynamo." The crank shaft of driving pulley

(Concluded on page 8.)

OCTOBER 21, 1882.

THE EDISON SYSTEM OF ISOLATED LIGHTING.

[Continued from Page 5.]

is lengthened out and forms the armature shaft. This machine is capable of maintaining 1200, or, in an emergency, 1000 lamps of 16-candle power each. Six of these large machines are already installed and in operation in the "First District" in New York. The current produced by all the Edison machines is perfectly harmless to the person as well as to property and can be taken by a child with perfect impunity. The reason for this is that the electromotive force (analogous in some measure to pressure in a steam system) is extremely low and is very nearly constant and independent of the number of lamps burning; it is the same on the various sizes. The quantity varies very nearly in

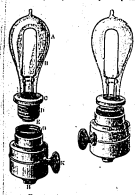

FIG. 1.

FIG. 2.

proportion to the lamps in use. On the arc system, on the contrary, the quantity of current is very nearly constant, while the electromotive force varies nearly as the number of lamps in circuit. Moreover when the two brushes on the arc machine are touched simultaneously, thus forming a complete circuit, a "counter electromotive force" is set up, which is many times the original. Thus a nervous shock is produced causing death. This "counter electromotive force" cannot be set up in the Edison system, as the circuit was already complete through the lamps; one more path was simply opened to the current. It is a separate power, but it is not necessary, as the power can be applied by means of countershaft from engine or wheel already in use. The power required to drive the various dynamos is as follows: 2, 9 horse power; 1, 30 horse power; 8, 32 horse power.

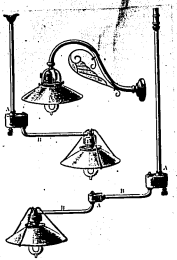

FIG. 3.

A very valuable feature in connection with the system, is the fact that by means of a flexible cord attached to a lantern, repairs can be made about any machine. At the end of this flexible cord is a plug which resembles the base of the lamp; by removing the lamp from the socket and placing the plug to which the cord is attached in its place, the current can be carried to any desired place.

The gas burners used in factories consume about four feet of coal gas per hour. One of these 16-candle power lamps is equivalent in illuminating effect to about two such burners, and in ordinary work will replace about that number; as, however, this would give about the same illumination as at present, some manufacturers, believing "that it does not pay to work in the dark," increase the number. It has been found by experiment that abundant and ample light is provided by using one 16-candle power lamp to four forty-inch looms, or by two wide looms (say 96 to 110 inch reeds) on wide goods, or the same for two ginghum looms. In woolen mills, the swinging bracket mentioned above, is found especially valuable. On this class of work one of these is suspended over each end of the loom, and so arranged as to swing in between the frames and the harness. This allows the weaver to keep run of the yarn on the bobbin in the shuttle box, and to "draw in" the yarn through harness, by swinging the lamp over the warp beam. On white or light colored woolens, two 8-candle power lamps per loom are sufficient. On dark colors, two 16-candle power lamps are used. The expense of lighting by the Edison system, as compared with gas, is much in favor of the former. Let us assume, for an example, a cotton mill of 35,000 spindles or about 900 40-inch looms, manufacturing sheetings and shirtings. This mill will require about 500 16-candle power lamps; the cost of installation will depend upon the length of mill, and also upon the position of the dynamo in relation to the work; but assuming an average mill, the plant will cost in the neighborhood of $6000. For this purpose we shall need two "K" (250 light) dynamos, requiring in the neighborhood of 64-horse power. Assuming that, in an ordinary engine, 21 lb. of coal

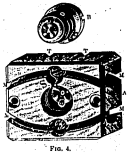

FIG. 4.

is the average hourly combustion per horse power, at $3 per short ton ($2000 lb.) the expense for fuel would be in the neighborhood of 32 cents per hour. The depreciation on the system is found first in the lamps, second in the commutator, and third in the brushes. The Journals run in Babbitt metal, and when properly oiled will show no appreciable wear. The lamps are renewed at a cost of $1 each. With an average life of 600 hours, as guaranteed above, the expense for lamps will be about 831 cents per hour. The commutator, composed of bars of copper about an inch thick, closely bound together and insulated from each other, with ordinary care will last 1500 to 2000 hours, say 1500, and can be renewed at a cost of $50. The depreciation on the two commutators will be about 6⅔ cents per hour. The brushes consist of copper wires bound together in the form of a spiral; these will last 100 to 200 hours, say 100, and cost $6 per set. The depreciation on brushes thus amounts to 10 cents per hour. Tabulating the above, we have for the hourly expense for running 500 Edison 16-candle power lamps, as follows:

Power—8-horse power, at $3 lb. coal at $3	.32
Depreciation—Lamps	.83½
" Commutator	.06⅔
" Brushes	.10
	$1.32

Let us now make a similar estimate on the cost of running 500 4-foot gas burners. At $2 per 1000 foot, this amounts to $4 per hour. Estimating 300 hours as the "lighting time" in factories in Massachusetts, we have a yearly cost for gas of $1200. At $1.50 per hour the Edison system will cost $474, showing a saving of $726, equivalent to a little more than 9 per cent on the investment. This does not take into consideration the interest on the gas-piping, nor the fact that the Edison system is furnishing twice the light of the gas. Assuming $50 (5 per cent. of $1000) as the interest on gas plant, and $480 as interest on Edison plant, the former, furnishing but half the light, costs 351 per cent. more than the latter.

In ordinary manufacturing work, the above 500 lamps will replace at least 750 4-foot burners. On this basis the Edison system can furnish a far steadier, safer, and more healthy light, and one which does not heat or vitiate the air, at a cost of 50 per cent. original gas bills (interest on gas piping being figured at $120—at 4 per cent. on $3000). The above basis of 300 hours is the average period of illumination per year where the ten hour law is in force. It is obvious that, where light is used for a longer time, the saving by the Edison system is correspondingly increased. In Rhode Island, Maine, and some other States, the annual period of illumination is about 400 hours. Under the above assumption that 500 Edison

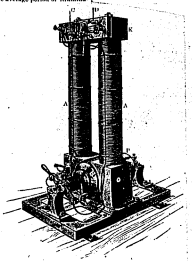

FIG. 5.

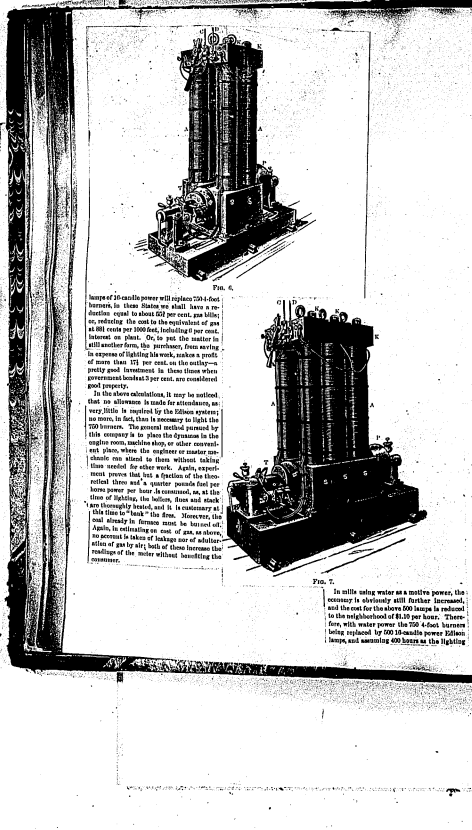

lamps of 20 candle power will replace 750-5 foot burners, in these States we shall have a reduction equal to about 62½ per cent, sss bills; or, reducing the cost to the equivalent of gas at 60½ cents per 1000 feet, including 6 per cent. interest on plant. Or, to put the matter in still another form, the purchaser, from saving in expense of lighting his work, makes a profit of more than 171 per cent. on the outlay—a pretty good investment in these times when government bonds at 3 per cent. are considered good property.

In the above calculations, it may be noticed, that no allowance is made for attendance, as very little is required by the Edison system; no more, in fact, than is necessary to light the 750 burners. The general method pursued by this company is to place the dynamos in the engine room, machine shop, or other convenient place, where the engineer or master mechanic can attend to them without taking time needed for other work. Again, experiment proves that but a fraction of the theoretical three and a quarter pounds fed per horse power per hour is consumed, as, at the time of lighting, the boilers, fires and stack are thoroughly heated, and it is customary at this time to "bank" the fires. Moreover, the coal already in furnace must be burned off. Again, in estimating on cost of gas, as above, no account is taken of leakage nor of adulteration of gas by air; both of these increase the readings of the meter without benefiting the consumer.

FIG. 7.

In mills using water as a motive power, the economy is obviously still further increased, and the cost for the above 500 lamps is reduced to the neighborhood of $1.10 per hour. Therefore, with water power the 750 4-foot burners being replaced by 500 16-candle power Edison lamps, and assuming 400 hours as the lighting

New Zealand Times, May 25, 88.

PARLIAMENT AND THE ELECTRIC LIGHT.

It is intimated that the Parliamentary Buildings will be lighted this session by Swan's incandescent electric lamps and Siemen's dynamo generator. The new lights are not expected to be ready for the opening of Parliament on the 14th June, but may be got into operation during the second or third week in the session. Swan's patent electric lamp, known as the Incandescent, differs somewhat from the lamps which the agent of Edison's Company has just fixed in the Government Printing Office, where they have been inspected by Ministers and other persons of note, and pronounced to be a successful application of the electric light to workshop purposes. It is remarkable that two different systems of electric lighting have been adopted by the Government, not as the result of careful consideration made by Wellington, but for other reasons. Edison's Company recently entered an action in the Supreme Court against the Swan Company, for alleged infringement of patent rights, and we understand the latter is now due for hearing. The allegation is that Swan's incandescent lamp is an infringement of Edison's lamp as patented in America, Europe, India, and the colonies; that the principle of both lamps is the same, any differences being in details that are not essential. The dispute between these rival Companies has been going on many months, without either side consulting the public; and now the Edison Company are seeking to compel the Swan Company to pay damages and make an apology. During this dispute it has been claimed for the Swan Company that any resemblance between the two lamps is accidental coincidence, and that the Swan lamp is the product of independent experiment. It is stated, on the other side, that none of the Swan lamps have been sold in America, where the question would be tested according to American patent laws. As to the point we have no independent information.

The lighting apparatus ordered for the Parliamentary Buildings is expected from London per the next direct steamer (the Arawa is the next), which leaves the docks to-day fixed for the opening of Parliament. The apparatus has yet to be tested, and a week or two days will be necessary to fit and test it experimentally. The new brick building which the motive engine and the dynamo generator are to be fixed is already finished, and a tube is laid to carry the electric wires from the engine room to the main building. The first temporary failing of the wires and lamps will be a slight but rapid operation, requiring only a few days, and as the incandescent can be readily placed, which is the engine-room, the House of Representatives and the Legislative Council Chamber may be illuminated with the new light within ten days or fortnight after the electric plant is landed at the wharf.

All the numerous rooms in the Parliamentary Buildings are not to be fitted with electric lamps in the first instance. Only those actually used for legislative purposes are to be first fitted with the Swan lamps, also the large new corridor, better known as the members "lobby," and probably also, the bookcase and new dining room. Other rooms will have to wait their turn, the first consideration being to get the main state of the building. The mode of illuminating the Council Chamber is to be by a number of skylights placed about central glass reflectors radiating downward, but by a number of small lamps fitted rather low in modern pendants thereby resembling gas-jets, and producing an ease of eyesight, no intense central glare. Not only the customary arrangement of jets, more brilliant than gas, and diffusing a pleasant whitish illumination in all parts of the large chamber. This convenient distribution of the electric light in small jets or "glow lamps" is the perfection of quality which Edison, Swan, and other inventors sought so long to

Hims per year, the annual cost of the electric light, including interest on original outlay, will be equivalent to gas at 75 cents per 1000.

For domestic lighting the Edison system commends itself especially to the attention of householders; for, with the electrolizers and the brackets manufactured by this company, the wires are entirely concealed, and there are no noxious gases given off to vitiate the air and tarnish the metal bangings of the room, and no smoke to blacken the walls and ceilings. Table lamps are also manufactured and in use, which are connected by means of a flexible cord to the chandelier, and can fill any purpose now occupied by the drop light. Meters are also used; these are virtually electrolitic cells. Each meter contains two cells, in each of which are suspended two zinc plates. One one-thousandth of the current used in the house is diverted through the first cell and one six-thousandth through the second. By the laws of electrolysis a current of a given strength will deposit a fixed amount of zinc per second. As the zincs are carefully weighed before using, the accumulation of zinc on the negative pole shows the exact amount of current used in the house. The second cell is a check upon the first. As these cells might be placed in position where the sulphate of zinc solution would be frozen, an automatic arrangement is provided which will meet this difficulty. It consists of a bimetallic spring made of brass and steel. This spring is set at 100°; the coefficient of expansion of brass being greater than that of steel (that is, the brass expands or contracts more quickly than steel), any change of temperature will tend to produce a curve in this spring and thus force the coil against a contact piece, throwing into circuit an Edison lamp beneath the cells; by the slight heat produced from the lamp the mixture in cells is heated above freezing point; this heat also acts on the spring, which gradually straightens and thus shuts the GO? is reached contact is broken and the lamp thrown out of circuit. Thus no part necessary to the completion of the Edison system, appears to have been overlooked by its originators, and the system now stands before the public perfect and complete in all its parts.

Hartford Daily Courant, Aug 3, 83.

The American Electric light system which is in use in this city is to displace the Westinghouse. Messrs. Rowland and Harris, who are attempting to introduce the Edison Incandescent light in this city, have had a canvass of the city made to ascertain the probable amount and distribution of the light required. The necessary data are now being worked out and will shortly be ready for the examination of those intending

which, and now that each separate lamp can have its current turned on or off with a small key, without affecting the other lamps which the same connected circuit, every condition of safety seems to be satisfied. The new light is, in fact, simpler to control, is certainly safer, and is cheaper than gas. It is also steadier, and a glare is as subdued as not to be unpleasant, even when the eyes are near, as when the light is used for nice operations in a workroom or at a writing-desk.

Siemen's dynamo machine is to be used as the electric generator in connection with Swan's lamps. The generator differs from Edison's dynamo, now used on the premises of the Government Printing Office, though it is on the same fund with mechanism for regulating the balance of light when any one-half the lamps in a connected circuit are suddenly put on, or shut off the main current, thus producing a jump until the regulator restores the average degree of illumination. Suppose 20 lights to be used in a building, that only a few are "lit," and that suddenly the whole number are turned up for immediate requirement, the result would be to diminish those few which were being first used, and to reduce the intensity of light required for the whole, just as if the main tap at a gas-meter were turned half down, thus reducing the pressure connected with it. The regulator applied to a dynamo will control the strength of an electric current in the same degree, or shut it off altogether. This can be done without varying the speed of the engine which drives the generating force, and which must be kept up to a certain speed so long as any lamps are in use. It is well understood that the electric force, or energy, supplied to a circuit is not consumed, but that it is not usually done; because of the imperfections which in theory exist, a waste which cannot be prevented with the present comparatively low efficiency of electric mechanism.

It is a pleasing fact in this connection that Mr Leonard has had a small electric apparatus fitted in his private residence, this being the first application of the new light for domestic purposes in this colony. He has adopted Swan's lamp and Siemen's generator, the motive power being a small gas-engine. The engine just placed in the Government Printing Office for the new light is driven by steam, and is 12-horse power. We believe the Gas Company offered to supply gas to Ledges for the use of the engine, but Mr W. J. Rowe, the agent for Edison's Company, has absolutely refused to supply it. Many lights are required, because, as he puts it, the engine's resistless power is applied to more than if driven by intermittent explosions of gas.

Boston Advertiser April 17.

Electric and Gas Lighting.

An interesting meeting of the Society of Arts was held last evening at the Technology building. The subject of electric light as compared with other artificial lights was considered in its practical and economical aspects, so far as scientific principles might illustrate it. Professor Crocker, of the institute, delivered a lecture, with a large number of illustrations, on the subject. Mr. Edward Atkinson, 20 Broadway, Messrs. Hayes, and Nie, Julius of Pall Mall, spoke, the two latter gentlemen representing the Edison Electric Light Company. Mr. Atkinson claimed that the price of gas light as one of the indispensable lights of the world was to be reduced one-half. Mr. Julius, in a paper read by Professor Crocker, claimed that each lamp in special use and chemical action was necessary. The great difficulty which was said was favorable to the incandescent, was the breaking of the carbon in the vacuum, and it was claimed that wires, both for arc lights and incandescent lights, may save, ingeniously be carried under ground.

Hartford Post, June 9, 88

THE EDISON LIGHT.

Interesting Test Recently Made to Consider the Difference between the Illumination in Hartford, 500 Seven twenty-five of twenty gentlemen met, by invitation in the Charter Oak lighting hall on Friday night, to consider the Edison incandescent light with special reference to the possible formation of a Company for its introduction in this city. Mr. J. Hastings was made chairman and Mr. Charles M. Beach secretary. Mr. Hastings, Mr. Beach, M. Northumber Mr. F. B. Hayden, treasurer of the Edison company, was invited to explain the system.

Mr. Hastings began with a statement as the difference between the arc and incandescent light being particular stress on the electric motor, which is the key to the whole system of distribution of light. The motor of which he discussed, and it seemed that the fire risk was less than on buildings otherwise lighted, and that as for as danger of personal injury was concerned the full force of the current might be received without injury and with no more than a modera shock. The lamps are [illegible] and the [illegible] [illegible] [illegible]

Metropolitan (London)
Sept. 15, 88.

lamp when the carbons have been pushed to their distance limit. A safety switch is mounted on the upper portion of the lamp bracket, which comes into use in the event of any accident occurring to the working parts of the lamp, such as an entanglement and being unable to relight, the circuit is completed, and the remainder of the lamps on the same line are unaffected. Fig. 3 is a sketch of the carbon rods and the carbon pencil, which passes through the hollow one for the purpose of igniting and relighting. As mentioned above, this is either accomplished by pulling a string, lifting a weight or automatically by electrical means, and therefore it is quite unnecessary to enter into minute details as regards this portion of the apparatus. It is to be hoped that the illumination of a portion of South Kensington Museum with the forty lamps will terminate successfully, and that through this means the Sun Lamp and Power Company may be enabled to bring this very effective and attractive light into greater prominence than heretofore. The type of lamp devised for workshop and factory use is most simple, and must necessarily be extraordinarily cheap. It should therefore attract more attention amongst engineers, shipbuilders, mill-owners, and others of like pursuits, than it has yet had recorded.

Fig. 3.

The Electric Light.—A very considerable amount of interest appears to be manifested on the part of the general public in regard to this subject. We cannot say that there is anything particularly new to announce in addition to what has already appeared in these columns, but there are two or three matters having reference to the general question which may be of some interest at the present juncture. Concerning Edison's invention, the subjoined paragraph appeared in Thursday's *Times*:—

> THE ELECTRIC LIGHT.—A correspondent writes: "Electric lighting appears to have taken a decided step in advance—namely, the possibility of obtaining the brilliancy of any particular light in the circuit without waste of energy in doing it. I understand that a telegraphic intimation of this fact has been received from Mr. Edison, and is communicated to Monday's *News Letter* (Dublin) of to-day (Thursday). The telegram states on Mr. Edison's authority that each electric burner can be independently devised and brought to the utility of its element is obvious."

We can, of course, say nothing as to the grounds upon which these statements are based. We give the cutting for what it is worth. While referring to Edison's discovery, we may state that we have been favoured with a copy of the *New York Sun*, which contains an account of an interview with the inventor. Implicit reliance must not, of course, be placed upon statements made at interviews of this character; but they are occasionally of use, as indicating the nature of the particular experiments with which further information is desired. The following is an extract from the article in question:—

> "In being mentioned concerning the articles of incorporation of the Edison Electric Light Company, recently filed with County Clerk Anderson, of this city, Mr. Edison said that they proposed to light the city, public buildings, and private residences with electric light, and the electricity would be made by an or more factories on the Edison system of the city. Instead of manufacturing electricity at one central point, as gas companies make gas, there would be a number. Each station would have an engine and several electric generating agencies. "You know," put back and forth. Therefore, each station will have one grand return wire, with separate wires will connect, thus forming the complete electric circuit. I think that the engines will be powerful enough to furnish light to all houses within a circle of half-a-mile. We could lay the wires right through the gas pipes, and bring them into the houses. All that will be necessary will be to remove the gas burners and substitute electric burners. You may have a bright light or not, just as you wish. You can turn it down or up, just as you please, and can shut it off at any time. No match is needed to light it. You turn the cock, the electric connection is made, the platinum burner catches a proper degree of heat, and there is your light. There is neither blaze nor flame. There is no escaping nor discharging. I do not pretend that it will give a much better light than gas, but it will be softer and steadier than any known light. I do know now that it will be cheaper than gas. It will give no fumes nor smoke. No carbonic acid gas will be thrown off by combustion. It will be a great thing for composition, engravers, and all forced to work during but summer nights, for it will there not hardly any heat. Shades may be used the same as shades were employed, but these will be for use not necessary for heat. The wind cannot blow it out. There can be no gas explosions, and no one will be suffocated because the electricity is turned on, for it cannot be turned on without lighting the burner. A person may go to sleep with a gas flame lighted, and never awaken except in eternity." "How long since the conception of the idea?" I asked. "Well," Mr. Edison replied, "I have made no attempt to discover a name. I know that it can be measured, but it may take some time to find out how. I suppose that a man pays so much for so many burners whether he uses them or not. We find that this works an injustice, why I shall try to get up a meter, but I fear it will be very hard to do it." Mr. Edison says that electric generating machines could be placed upon steamboats and locomotives, and the boats and cars lighted by the action of the engines, but the instant that the machinery stopped the lights would go out. He thinks that it may be necessary to have an extra engine in each station in cities, to be prepared for accidents. If the first engine should break down, the second one could be used to feed the lights. Country towns, with the use of the electric generating machines, could be lighted by water power. Any power could be used, provided it was strong enough to turn the shaft of the machine with the necessary rapidity.

Later on, in the same article, the reporter says:

> The Professor then exhibited an electrical generating machine. It is what is known as a Gramme machine. A knot of engineers crowded the cylinder facing each other. Wires were attached to it. Mr. Edison turned the crank with his shoulder, and the engine moved. In his manipulations he began to turn the cylinder. He touched the point of the wires, and a small piece of metal near the cylinder caught, and there was a flash of blinding white light. It was repeated at each touch. "It is the most intense power I ever saw in an electric light," he said. "But how do you utilise the light? was the next inquiry. "Oh," replied the Professor, "that's a question with a pleasure. In an adjoining room a single key was placed in one of the three ordinary keyholes in one of the walls and turned a little. Two of the burners attached to a hanging chandelier in the centre of the room immediately glowed faintly, and as the key was turned still further around the glow increased, until a brilliant and perfectly steady white light was obtained, equal to the light of twelve ordinary gas-burners. The key was then turned in the reverse direction, and another of the lamps was lighted up. In the same way the fourth and fifth burners were lighted, and there resulted an exceedingly brilliant white light, yet so soft and steady that it did not pain the eye. The lights were easily turned to any desired degree of brilliancy—from that of a mere spark to that of a light ten times the intensity of the common gas jet, that being the maximum power of the lights in use. The experiment of the facility to easily fit up lights with a thirty gas burners. By a very simple "switch" in the wall the current of electricity is divided and subdivided to supply any number of burners desired, the electricity reaching the switch from the generator through a single wire. The switch has the faculty also of regulated to any degree, merely by turning a key, which operates upon the switch in the wall. Mr. Edison, in explaining the working of a number of patents, one of which is the points of their new electric switch now in use, the property of a joint-stock company, recently introduced into Paris, and which is in use in the Grand Opera House. He explained the establishing of central stations in various parts of the city, from which powerful electric generators will supply the necessary electricity. The company claims to be able to supply the electricity at one-fourth the cost of ordinary gas. The difficulty of a meter has been overcome by the invention of a meter which will record the number of burners used in any given house, and the number of hours each burner is lighted. The measurement of the electricity used would involve such complicated and delicate instruments that the time plan has been adopted.

As we have before remarked, the Government appear to be devoting considerable attention to this subject, and accounts reach us of trials at Woolwich and Portsmouth, accounts which are rightly informed, have yielded results which, to say the least of them, are eminently encouraging. Information of importance also reaches us from the provinces, all tending to show the desire that exists in all quarters to render the electric light an article of practical public utility.

Metropolitan (London)
Sept. 15, 88.

Improved Street Lighting.—information reaches us from Bristol of a most interesting experiment of carrying out in that city on Tuesday evening last, for the lighting of the streets by the employment of reflectors for the gas lamps, the result, as we are informed, being the production of 50 per cent. more light with a less consumption of gas. It appears that, owing to a suggestion from the Corporation when the scheme of electrical lighting was under discussion, Mr. R. Kirk, the gas engineer to the Corporation, turned his attention to the means of improving the present system without involving any extra consumption of gas; and, as we understand the particulars furnished to us, he has succeeded in obtaining the object in view by the following means:—Dealing with the present burner, which consumes five cubic feet of gas per hour, and is in general use throughout the country, he divides the light into two jets, each consuming 2½ ft. of gas per hour, and thus leaves the actual consumption unchanged. Between these two jets placed in each street-lamp, he suspends a double convex lens, forming a powerful reflector, and, by competent calculation, the result is found to be an increase of lighting power to the extent of 50 per cent. Ordinary bat's-wing burners are used, and the only care required to insure a perfect light is a nice adjustment of the suspended lens, so as to get the right focus and the full reflection of the light. When this is obtained, we are assured that the jets, even at a distance, are very brilliant, and have the appearance of globes of light. We are told that they illumine the footpath between each lamp with much of the effect of the electric light, while the divided jets give ample light also to the roadway. A special feature of the system is the long distance to which the light is thrown from each lamp, and at 150 yards, it is asserted, the light backed by the reflector is very powerful: compared with the ordinary street lamp, while a slight increase in the size and capacity of the burners has a surprising effect. In two or three instances Argand burners were tried; the light was more steady, but showed little improvement on the ordinary bat's-wing burners which, it appears, are found sufficient in all practical purposes. We understand that the gas engineers of Corporations in other provincial cities have been more slow—waiting the result of the bristol scheme, and several letters had been received from their engineers asking for information of its practical adoption. The plan was considered undoubtedly a success, and will probably be adopted very largely in the streets of the city.

The Electric Light at a Distance.—A correspondent informs us of an interesting and successful practical experiment that was recently carried out at Saratoga Springs, New York, for testing the extent of the illuminating power of the Maxim Electric Light, and if the particulars forwarded to us are only approximately correct, the results obtained, to say the least of them, are eminently encouraging. It appears that the experiment was made in operation over the Grand Union Hotel. An open parabolic reflector was used—no lenses—and care was taken by Mr. Maxim to set the points of the carbons a little on one side of each other, and to adjust them exactly to the focus of the reflector. After having been accomplished, the light was turned toward a spot in Bulmer Spa, New York, 74 miles distant, where, by previous arrangement, a group of several hundred persons were assembled to witness the experiment, which the result, as we are informed, that the place was instantly illuminated in such a way that ordinary print could be read, the time seen on watches, &c. The night, it is stated, was clear, still, and dark. The experiment was made at about half-past nine o'clock in the evening.

The Metropolitan, London, February 19.

Electric Lighting on Waterloo-bridge.—Last evening, the experiment of lighting this now much frequented thoroughfare by means of electricity was carried out with most successful results. Shortly after six o'clock, Mr. Drummond Brady, the Metropolitan Board of Works' Mr. Keates, the consulting chemist to the Board, and several other gentlemen more or less interested in the progress of electric lighting, assembled at the temporary shed on the Embankment adjoining the Charing-cross Railway Station, where the apparatus is fixed; and, after inspecting the arrangements made for the employment of the additional lamps on the bridge, exactly at half-past six o'clock when in popular language may be termed the day was applied, and instantly the roadway of the bridge was brilliantly illuminated. An electric light was provided alternately with the gas-lamps, and additional lamps were brought into use and placed at a considerable height in the centre of the roadway. The effect was most satisfactory in every particular, and the crowds that assembled loudly testified their appreciation of the improvement on the old mode of things that the light effected. It was particularly noticeable that the *façade* of Somerset House came out in quite an artistic style. It may be mentioned that the engine now employed in the shed at Charing-cross is the same one of 20-horse power supplied by Messrs. Ransomes, Sims, and Head, of Ipswich, as was used at the commencement of the experiment on the Embankment for only 10 lights. It now supplies the motive-power for no less than 55 lights, and when the arrangements have been completed for lighting up the offices of the Metropolitan Board of Works by this means will serve 60 lamps.

Metropolitan, July 80.

Electric Lighting on Shipboard.—A very successful application of the electric light has been exemplified in the Gravesend on the 24th ult. for Australia. The installation consists of a Gramme machine, generating the current, by which seven incandescent lamps are worked. Four of these are fixed in the main saloon, and the remainder in the steerage, where this mode of lighting is a great desideratum. The lamps are placed in series, but a resistance coil and automatic switch renders each independent of its neighbour. Several spare lamps are carried, which can be worked from one to a Gramme arc lamp, which is contained in a special lantern fitted with a reflector. This will be used when intimating power of the large lamps is 2,000 candles, while each of the small incandescent lights is about 20. The superintendence of Mr. Killingworth Hedges, C.E., the installation has been carried out under the auspices of the British Electric Light Company. The extension of the lighting to the other parts of the ship, we are informed, will be completed on her return.

Electric Lighting at Railway Stations.—Progress is slow, but in our opinion none the less sure, towards that perfection of the electric light which most people would desire to see. The value of the light itself for lighting large spaces has been fully established, and chiefly to extensive areas its use has hitherto been confined. At the present time, however, the attention of a large number of illuminating railway stations is on its trial at the Aldersgate-street, on the Metropolitan Railway; and should it prove satisfactory to the directors it will lead to a great improvement, inasmuch as similar means of illumination will be employed at several of the other underground stations in London. A number of gentlemen interested in the experiment met on Tuesday evening at Aldersgate-street Station, where the arrangements for producing the light were shown and explained to them by Mr. M. Fenton, secretary to the railway company; Mr. R. Godfrey, engineer to the Electric Generator and Light Company, Mearnsie-street; and Mr. C. F. Varley, whose firm (Messrs. Harding and Co., Paris) manufacturing the apparatus for producing the Lontin light. That is the light used at Aldersgate-street, where eight lamps give a light vastly superior to the old gas system. In this respect the railway authorities are quite satisfied, but they wish to know the comparative cost of the electric light as cost as compared with gas. The Electric Generator and Light Company state that the present brilliant illumination of Aldersgate-street Station can be maintained for as little cost as was incurred by the old-fashioned flare gas lamps, and should the railway company be satisfied with less brilliancy, than the cost would be less than that of gas. The engine which works the electric machine, however, is of much greater power than is actually necessary for its present purpose; but the Electric Generator and Light Company have hopes that it may be utilised to help in producing electric lights, not only for Aldersgate-street Station, but also for Moorgate-street and Farringdon-street Stations, for Smithfield-market, and the Great Western Goods Station under it, and for the Midland Goods Station. Our readers will remember that a few months ago the Lontin light was applied at the Coiety Theatre, but since that time, we are told, it has been improved in various details. Its chief advantages are the low speed at which its machinery works, thus reducing wear and tear, risk of accidents, and overheating; the readiness with which the light can be divided; and the production of alternate currents. The number of different circuits which one machine can generate, and the number of separate lights obtainable from each circuit are only limited by the size of the machinery. A valuable feature in the invention is that each light can be regulated or put out without affecting the others. The lamp is an important part of the apparatus. It is also known as the Serrin, with Lontin modifications. Those at Aldersgate-street Station need the carbon renewing every four hours, but by an improvement lately made carbon sufficient for 8 hours can be supplied. In two respects, at least, these lamps are commendable. They neither show changing tints nor cast the shadows of the carbon sticks within. It is claimed, moreover, that the light they give is steadier than any other. As the light was seen on Tuesday night at Aldersgate-street, certainly little remains to be desired as far as brilliancy, steadiness, and softness are concerned. The exhibition indeed was very interesting. The electric lights were extinguished and the gas turned on to the customary extent, and it is hardly necessary to add that the contrast was very striking. Then—the electric lamps having been re-lighted—the gas lamps were lowered without any perceptible difference in the brightness of the premises. Next a circuit was extinguished, the remaining lamps being left burning, and then one lamp was lowered, each other member of the circuit shedding its light undimmed. It was stated that the eight lights cost 1s. 2½d. an hour, although we presume that this is only an approximate estimate. There are thirty-six gas lamps burning at the station when the electric light is not in use, each consuming 5ft. an hour; that is to say, costing roughly 9l. an hour. The Metropolitan Company, however, appear to be of opinion that the increased brilliancy cast over large areas would make up for the extra expense, and that a larger diffusion of the light would render it relatively cheaper; and, moreover, improvements are now in progress aimed at cheapening some of the appliances, and which may, it is thought, reduce the cost of production. Our readers will see from the particulars above detailed that this subject continues to occupy the most earnest attention of scientific men. On every occasion when an experiment of this kind is undertaken, further improvements of some kind are shown bringing us on every occasion, it is fair to presume, nearer the result so devoutly wished for.

Metropolitan, Feb. 5th.

The Brush Electric Light.—We had intended this week to give a full description, with illustrations, of the Brush system of electric lighting, but pending the receipt of certain statistics with reference thereto, with which we had hoped to be favoured before now, we are compelled of postpone any further reference to the subject until our next issue.

tion at one or more lamps, or, indeed, their removal altogether, does not affect the others except (if the machine be driven at the same speed) to make them brighter, but by driving the engine slower, and therefore using less steam, the same initial degree of illumination can be maintained in each of, say, fourteen lamps, as if all the sixteen were in operation. The great simplicity of the Brush lamp consists in the fact that the feed is actuated by gravity alone, while it is controlled solely by the influence upon a bar of iron of a magnetic field, the intensity of which varies with the strength of the electric current passing through the lamp circuit. The general external appearance of two forms of Brush regulators is shown by the accompanying engravings, for which we are indebted to our able contemporary, *Engineering*. Fig. 1 represents the single

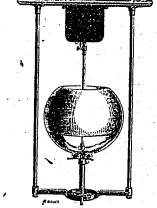

Fig. 1.

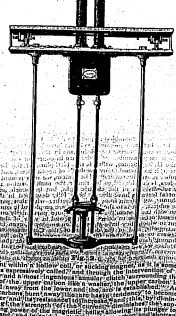
carbon or eight-hour lamp; and Fig. 2 the double carbon or sixteen-hour lamp, with the glass globe removed. In both these lamps, which are designed for general illumination, the lower carbons are fixed, and as they burn away the upper carbons follow them, so the arc gradually descends; but for certain special installations, such as lighthouses, or for purposes of projection, a focus-keeping arrangement has to be applied. Like most of the modern electric lamps, the upper carbon descends by its own weight until it sets the lower carbon, and the circuit is thereby completed; the effect of this in the lamps we are describing is to cause a soft iron plunger to be drawn to a more or less



in position. The foregoing description is necessarily given in somewhat general terms, but it is probably sufficient to convey an idea of the nature and purposes of the lamps in question. All who are familiar with the great difficulties which hitherto have appeared to be almost insuperable from the burning of several lights in a single circuit, will know that a number of regulators constructed in the manner described, and with no other complication or contrivance, would scarcely be capable of burning uniformly in a single circuit, and it is on account of the simple and ingenious method by which each lamp controls itself independently of the action of all the others in the circuit, and yet dependently on the strength of the current in that circuit, that constitutes the merit of the originality and the great perfection of the Brush regulator. The carbon points employed are, being solid rods, about 8 in. long, and are electro-plated with a thin covering of copper; they are, in fact, about eight times as heavy as those used for the ordinary arc lamps, which weigh about 9l. in. of the positive and about 4 in. of the negative carbon are consumed. When, however, the lamps are required to burn for a longer period double carbon lamps are employed, fitted with two pairs of carbon holders, as shown in Fig. 2, and each is controlled in the same way as in the single carbon lamp, but the controlling apparatus is not duplicated. When the lamp is put into action the arc is formed between one of the pairs of carbons, and when they have burnt out the other pair automatically starts into action and continues to burn until it is in turn consumed; in this way the time of burning is doubled, and in order to extend the period of burning, it is only necessary to employ a lamp with a third pair of carbons, when it will be capable of illuminating for twenty-four hours, each additional pair of carbons extending the period of burning for another eight hours. The Brush system of electric lighting, we may add, in conclusion, is remarkable as being, we believe, the only one which is capable of maintaining a large number of large arc lights in a single circuit, and it would be difficult to over-estimate the great value of this distinctive property for the purpose of public illumination. Under other large arc systems each lamp must have a separate machine, and there must, of course, be as many regulars of leading wires as there are lamps and machines. It possesses also another very special advantage, and that is that a series of lights may be maintained by the Brush system at a great distance from the machine, and with a remarkably small loss, and this is of especial advantage where several lights have to be employed, because if there are as many long conductors as there are lamps, then the whole of the loss of current due to the resistance of the cables must be borne by each lamp; whereas if a number of lights can be included in a single circuit, the loss of current from the resistance of conducting cables is equally divided among all the lamps in the series. With respect to this part of the subject, it is an interesting fact that the sixteen lights which are now in regular use for the illumination of Charing Cross Railway Terminus are actuated by a machine working in the Anglo-American Company's works in Lambeth, and that within a few weeks a large area of the City of London will be illuminated by the same system by four lamps, all actuated by one circuit by a machine working in the Lambeth works. On a future occasion we hope to be able to describe at length the arrangements for this important adaptation of the light for the lighting of our public thoroughfares; but from what is given above, in addition to what has previously appeared in these columns, we have our readers will consider us fully justified in the observation with which we opened—that this light, having successfully passed the experimental stage, has now asserted its right to be placed among the practical lights of the day.

MAY 6, 1882.

THE METROPOLITAN.

THE Gulcher System of Electric Lighting.—Although at the late Electrical Exhibition at Paris the system was awarded a gold medal, it has remained until within the last few days comparatively unknown. Mr. Gilcher, however, has since been engaged, we understand, in improving his system in various particulars, and now that it has been formally introduced to the notice of the public, we anticipate that its undoubted merits will speedily obtain for it that attention and recognition to which it seems to us justly entitled. A demonstration on this system has been effected at Messrs. Ransome's works, in King's-road, Chelsea, and, in the light his here been in operation for several weeks past, an opportunity is afforded of judging of its practical value. Messrs. Ransome—who, by the way, assure us that they have no interest whatever in the system beyond a desire to light their works efficiently but economically—report themselves eminently satisfied with the result of the experiment so far, and on the occasion of a private view on Monday evening, by a number of gentlemen interested in the subject, the lighting was unquestionably all that could be desired. There are altogether eight 100 lights of about 2,500 candles each, and they burn with extreme regularity, not the least flickering being perceptible. The current is supplied from one of Mr. Gilcher's improved dynamo machines, which absorbs nearly 14-horse power, and three of Swan's incandescent lamps are also introduced, with the view of showing the adaptability of the system to other methods of lighting. Mr. Gilcher's dynamo is of peculiar construction, the leading principle being, however, the production of a current of low tension and great quantity. The lamps in use are of great simplicity, and burns for over seven hours without the carbons being renewed. Among the advantages claimed for the Gilcher system are that the light produced is clear white, without the green tinge which peculiar to some lights, tension current; that the regulators, in consequence of their great simplicity, can be produced at a low price; that of the lamps inserted in circuit, any required number can be extinguished and re-lighted without influencing the working of the other lamps or requiring any other apparatus; that the required power of the dynamo-electric machine is proportional to the number of the lamps being lit at any time by it; that the insulation of the conductors may be simple, and, finally, that the service of the lamps while working, and also the teaching of the appointed parts of the conductors by inspectorial parts of the body, is found to be all designed. Mr. Gilcher apparently succeeded in satisfying all those assembled at Messrs. Ransome's works on Monday evening that his system really does possess these advantages.

ANOTHER ELECTRICAL EXHIBITION.—It is announced that an international electrical exhibition will take place shortly at Munich, in which all the appurtenances exhibited will be constantly at work in sight of the public. Gramme machines will be used, the machine power being obtained by means of a natural waterfall situated more than three miles from the Public Garden, wherein the exhibition will be held.

HOLMES'S ELECTRIC LIGHT AND MOTORS.—In the Common-room at the Capitol Palace, on Wednesday evening, Mr. Holmes, the representative in England of Mr. Edison, delivered a lecture, before a crowded audience, upon the subject of Mr. Edison's efficient light and motors. In doing so he illustrated with the aid of dissolving views the construction and working of the machinery necessary for the production of the electrical current by supplying light and power to dwellings. The experiments were made with a view to showing its simplicity, and also its perfect safety. Care is taken, it was pointed out, to keep the wires perfectly insulated, while if they should by any accident become partially subjected to the earth no damage would be done. The ballasting is entirely extinguished, and no harm would result. By a judicious distribution of the electric as well as by a number of incandescent globes hung from the balcony. At a given signal these lights were all turned down almost to vanishing point, like the sunlight at the theatres when a "dark" scene in a melodrama is to be presented. Again peculiarities these were not only turned on and off at will, but whole clusters were simultaneously lighted and relighted by touching of an ordinary electric switch. The perfect safety of the new illuminant was strikingly illustrated by the lecturer. Placing a piece of gauze over one of the globes containing a sixteen-candle light, he proceeded to smash the glass with a hammer, and the result was that the light was extinguished without scratching the material. The current itself, it was affirmed, could be safely applied to the eye-lights, might pass through the human body without the slightest harm being done. In many cases people who had tried the experiment were unable to feel the slightest shock. The working of Mr. Edison's motor for measuring the electricity supplied to houses was next explained. Mr. Edison's system of working machinery by electricity was shown in practical operation, and a clock log of wood was quickly sawn lengthwise in two in half. Proceeding to deal with the subject of Mr. Edison's electric railway, the lecturer showed a portrait of the locomotive in contemplation upon the three miles which have been completed. With the exception that no fenced was to be discovered, the engine was very similar to those in use upon the American railways, was carried on two-cabins and all complete. The inventor, it was stated, was engaged in perfecting the apparatus, and had expressed it as his opinion that in a few days it would be fully entirely experimental upon open railways. In conclusion Mr. Johnson said a few words upon the subject of Mr. Edison himself, and the kindly criticism of which he had been the recipient. Something had been said about his selling his shares in electric lighting and other companies and is only devoting in gas shares. It happened, however, that Mr. Edison had in such matters one of the most simple-minded of men, and had never bought or sold or had any interest in any gas shares. As to his selling his shares in electric lighting companies, it was not until the last few months that he had busied with any of them, and then he had given up those as he expenses of his great establishment that which he had undertaken to supply the whole world with electricity.

Metropolitan, Aug. 25, 83.

ELECTRIC LIGHTING AT THE FISHERIES EXHIBITION.—On Wednesday night some important and striking additions were made to the electric lighting of the International Fisheries Exhibition. The chief feature of the display was the Hockhausen lamps on the north end in the open ground of the gardens, and placed at an altitude of 120 feet, with an effective candle power of 50,000, the effect of the cluster of six stars was surprising, and is said to have established for a full harvest moon, being distinctly visible in many parts of London, even as far as Clapham-junction and Holloway-park. Another feature was the efficient lighting of the Canadian court, by a few lamps of 2,000-candle power each and of which are admirably suited for the study and library.

The Metropolitan (London) Daily, 88.

ELECTRIC LIGHTING IN THE CITY.—Much regret has been expressed at the announcement by the directors of the Maiden-Westall Company of their intention to discontinue for the present the lighting of that portion of the City which for some years past has been so successfully illuminated by means of Wetton arc lamps. The reason given by the company for this decision are based solely on the question of expense, it being very reasonably pointed out that it is but impracticable for an electric company to maintain a centre and staff to light a few arcs, and it would be for a gas company to do so profitably. Until, therefore, the Commissioners of Sewers extend their operations to allot of the City in less sections in accordance with the terms of their advertisement issued in October last, "the ordinary gas lamps are to be substituted for electricity in the area originally assigned to this company." Such a course can be dealt, however, but even a temporary suspension of the present mode of lighting will prove an exceedingly unpleasant and considerable alteration to those who have occasion so be in the City after dusk. Of late Queen Victoria-street has become perhaps the best lighted thoroughfare in all London, and it will be felt by most people that the present brilliant illumination should not be displaced by the more ancient but less efficient system of gas lighting. If by any reasonable means so undesirable a change can be avoided. We understand that the question will be raised at the meeting of the Court of Sewers on Tuesday next, and it is of course possible that arrangements may be made for a continuance of the electrical illumination.

DOMESTIC ELECTRIC LIGHTING.—Thurston House, Bromley, the residence of Mr. Swan, is lighted throughout with electricity, and forms one of the most interesting private installations yet made. It is, we believe, the first complete mansion, every room and corridor being lighted by the current: even the coal cellars, and the stables, have still been in use all commanded by small switches suitably placed so that a person entering a room, or leaving it, can at once light up or extinguish going and darken it on leaving again. The switches for this purpose are placed near the doors either outside or just within. There are between sixty and seventy lights on the premises, including two in the lodge-house. They are supplied by two Otto gas engines, each of 3-horse-power nominal, but capable of developing 5 horse-power. Each drives a Siemens continuous current dynamo of the smallest size, and from these Sellon-Volckmar accumulators are charged for an hour before the lighting begins. These accumulators serve to supply such lamps when wanted, the two dynamos only supplying thirty lamps when running on them alone. The accumulators can be kept partially charged by a bye circuit while the machines are running. They maintain the extra lamps required on special occasions, and also yield occasional lights during day. The engines consume 7 cubic feet of gas per hour, and this expended in gas lighting would give thirty gas jets of 15 candle-power; but the electric lights are rather over 15 candles (they are 20-candle lamps), and the light is far more pure, agreeable, and healthy.

ELECTRIC LIGHTING.—The Special Committee of the House of Commons, presided over by Mr. Holmes-Heath, to whom numerous provisional orders of the Board of Trade were referred, commenced its sessions yesterday, resuming on Thursday the consideration of Provisional Order Bill, No. 8, relating to the Brush Electric Company, including Sudeley, Mayfair, and Covent-garden districts. The question at issue was whether the Jablochkoff Company should be allowed to enter the district under a seven years' license granted to the Swan and Edison Companies, who are admitted by the provisional order. It was understood that the Board of Trade and the Local Government were in favour of the admission of the Jablochkoff, and that the two companies had come to an arrangement whereby they were to participate. —Mr. Jones, on behalf of the Jablochkoff Company, submitted to the committee that the local authority should have the right to determine how the district should be lighted. Evidence in favour of the admission of that company was given by Mr. Seaman, agent of the Duke of Bedford, owner of Covent-garden; Mr. Reeves, secretary and manager of the company, who stated that it is intended to light Covent Garden Theatre next week with the Jablochkoff and incandescent lights; Mr. Clarke, one of the managers at Messrs. Shoolbred's, who declared that the Jablochkoff light had worked extremely well since the establishment for two years, and was easily superintended; and Mr. Hill, the oldest member of St. James's vestry, who stated that all his colleagues whom he had spoken to were in favour of the admission of the Jablochkoff. The Telegraph Construction and Maintenance Company, evidence was given to show that were time given for the admission of that company, electricity could be supplied by them at the rate of 5s. for light equal to the illuminating power of gas, as compared with 10s. 6d. of the other companies.—Mr. Andrew Chubin, of the firm of Coutts and Winfrey, and Mr. St. Martin, secretary of the Junior Carlton Club, gave evidence in favour of that company. The committee adjourned.

The Metropolitan, April 21, 88.

ELECTRIC LIGHTING IN CLERKENWELL.—At a meeting of the Clerkenwell Vestry, held on Thursday evening a report was presented by the Special Purposes Committee stating that they had had under consideration a letter from the secretary of the Maiden-Westall Electric Lighting Company, a position of which letter was as follows:—"According to an interview our managing director, Mr. H. Watt, recently had with the Clerkenwell Vestry, we have pleasure in calling your attention to the lighting of your district with our electric system, and, judging by the favourable opinion then expressed that a change from the inefficient to the new lamps would be desirable, I am desired to request that you will kindly present to consideration at an early date of the incandescent ones you have now in use; these, being each of 20 candle power, would give five times more light than a wax candle of 4 to the pound. The charge for the 'size' would be 4d. per week for the incandescents, subscribers to use as long about 1s. Of course your lamp, the same as the company's expense, and could be turned on and off at will." In a reply to the company the chairman of the committee (Mr. Yates) had pointed out that, although the Vestry had sanctioned the laying of the St James's Company in the City of Portsmouth-road by incandescent lamps of specified power, the company had generally failed to comply with the terms of their agreement, and that, therefore, the committee would be perfectly justified in refusing the Vestry to sanction the extension where the company desired to open. The company, however, seemed to have recognised the failure of the present system, and now made an offer to supply to are lights of great power at 4d. per hour, in place of the incandescents hitherto used in Portsmouth-road. As this offer seems increased safety, and as the incandescent system had been generally a failure, and the lights had not united that the company should give the Vestry the benefit of the incandescent. The secretary of the company subsequently wrote stating that he was desirous to the substitution of "arc" for "incandescent" lamps now in use in Penton-street, and that "duplicates were quite prepared to make the change at once, and to charge the same rental as for the incandescents." At the meeting of the Vestry on Thursday evening, Mr. Yates, after expressing surprise that the Vestry was in no way pledged to the adoption of the system, after the expiry of the present one, moved that the proposal of the company be agreed to.—Mr. Bowyer seconded the adoption of the report, and the motion was agreed to unanimously.

ELECTRIC LIGHTING AT THE HOUSE OF COMMONS.—The electric lighting experiments at the House of Commons were the subject of much discussion in the House on Tuesday evening. Mr. Colonel Alexander Churchill, Mr. Shaw-Lefevre (the Chief Commissioner of Works), and Mr. Edison Holmes, M.P., had their say in light the Directors and Engineers of the House experimentally all the rest under at the same time, at a cost slightly above that of gas for the same period, and which worked out at something under £100, they supplying the plant. Mr. (Mr. Lefevre) thought that the interval of sessions was too short to offer without entering into any further obligation to the system, with respect to the future he would, towards the end of the Session, consult the wishes of members before making any permanent arrangement. In the present state of electric lighting he did not think it could be adopted by competition. After careful consideration, he did not think able to act on this principle when he introduced the 3-wire system of lighting into the Law Courts.—Lord H. Churchill, having also inquired whether, before the Law Courts were lighted by the Swan Company, tenders were received from the Siemens, Edison, and Swan Companies, Mr. Shaw-Lefevre said that he had invited the Swan Company to light the Law Courts, and had not received tenders from the other companies. He added in reply to Viscount Folkestone that it was not intended to introduce the electric light into the House itself.

Electric Lighting Conferences.—In consequence of

communications having been received from various parties, light companies intimating their intention to apply for provisional orders to enable them to supply the electricity in the various districts in South London, the Vestry of Camberwell have just issued invitations for a conference of South London Vestries to be held in the Vestry Hall, Peckham-road, on Tuesday, the 31st inst.

Electric Lighting at Chiswick.—Mr. Woodhouse and Chiswick.—It will not be long before the electric light makes its appearance in most of the London suburbs. A deputation (Mr. Woodhouse and Mr. Rawlinson on the Solway Court Estate at Richmond are to be electrically illuminated, and the arrangements for carrying out the same will be settled in the same way. Bedford Park, in the neighbouring parish of Chiswick, will also be electrically lighted shortly.—*Local.*

The Vestry of St. George, Hanover-square, and the Electric Lighting Act.—At a meeting of the Vestry of St. George, Hanover-square, the Parliamentary Committee presented a report, recommending that the Vestry should apply to the local authority (in this case the Vestry) themselves to apply for a Provisional Order for enabling themselves of the Electric Lighting Act; and that application be made accordingly.—Mr. Lewis Berry moved the adoption of the report. He contended that it was necessary for the Vestry to act, so as to protect themselves and prevent companies obtaining powers very similar to those now exercisable by gas and water companies.—Mr. Lewis seconded, feeling that the Vestry should have the power in their own hands, if they did this they could make their own terms and enter into a contract with a company or companies to supply electricity; or the Vestry could take the whole matter into their own hands.—Mr. Jones said that as a member of the Parliamentary Committee he at first supported the adoption of the majority, which had been recommended to the Vestry. He had, however, seen reason to alter his opinion, for if the Vestry applied they would be landed in a large initiatory expense, and if they did not carry out all the restrictions of the Board of Trade they were liable to severe penalties. If he obtained the order they were bound to act, because they asked for it, and on the cessation of abuse. He moved as an amendment that the report be postponed.—Dr. Schidlof, stated that if the Vestry intended to apply for a provisional order it would be necessary to have a special meeting of the Vestry for that day month, and to consider what conditions would have to be instructed to do a lot of preliminary business.—The Clerk read a valuable report upon the subject from the pen of Sellon, and the rev. chairman said he did not think the Vestry could do better than follow the suggestion contained in the report—that was to oppose the companies and remain quiescent for the present. He suggested that the subject should be referred back to the Parliamentary Committee.—Mr. Lewis said that if a local authority desired a licence, it was not absolutely necessary that they should act upon it. They might remain perfectly passive. Under the 12th section of the Act it was not necessary that the local authority should carry into effect the lighting of the parish by electricity, but they might depute it to any company they might think proper to do it, to reply to a question, said that unless the Vestry resolved that day to apply for a provisional order, their opposition to the bill would be of no use.—Mr. Jones said he did not think they could not delegate their powers to any company unless with the consent of the Board of Trade.—The amendment was lost by 14 to 12.—The motion was then agreed to by 23 to 13.—It was resolved to hold the necessary special meeting of the Board on Wednesday, the 20th prox., and that the solicitor be instructed at once to take the necessary steps.

Metropolitan, Nov. 82.

The Vestries Hotel, at Barnes, has recently been lighted with, by Edison lamps, and the Edison installation. The Parliament, Shelbing at Cannons, completed in March last, appears to be giving much satisfaction. This installation comprises 44 lamps, 34 in the hall, and 10 in the strangers' gallery.

Metropolitan, Nov. 1882.

Dr. Siemens on Electric Lighting.—We exceed-

ingly regret that the exigencies of space render it altogether impossible for us to publish at any length to-day the very interesting and instructive address delivered by Dr. C. W. Siemens at the Society of Arts, on Monday evening, on the subject of electric lighting, but its general features may perhaps be briefly stated. After an opening allusion to the general principles which govern electric lighting, Dr. Siemens gives precise data for the belief that the establishment of electric lighting over the towns of Great Britain and Ireland would absorb a capital of £800,000,000 sterling; but that the manufacturing appliances required in order to produce work representing this value of machinery and, of what must necessarily be the result of many years of technical development. On these grounds alone, he believes that the ambition of the various electric lighting companies is in excess of their powers of performance; and that for some time to come they must be regarded rather as specific lative than as practical undertakings. He did not afford any information as to the scope for improvement which may exist in arc regulators and in the manufacture of carbons for incandescence; but he stated that the existing dynamo machines restore, in the form of electricity, ninety per cent. of the power expended in working them, and also that they will again restore ninety per cent. of the first energy in the form of motive power derived from the electricity. On the question of the probable cost of setting up a system of electric lighting, Dr. Siemens, who previously had been content to state his opinion, has now taken the opportunity afforded by his address to state the data on which it is founded, and thus to render it far more open to criticism than before. He believes that his conversion to a quarter of a square mile, densely populated, is as large an area as can be conveniently and economically covered by a single "installation." He selects St. James's Square as a type of such an area, and supposes that the central establishment should be situated in the open portion of Trafalgar-square. Proceeding on a density of occupation of the above nature, which would be required, of the number of lights the necessary conductors, of the cost of the engines and dynamos, of the expense of laying the conductors, and of sinking the mains, the author arrives at the conclusion that the annual cost of a sixteen-candle incandescent lamp would be just below 22s., its equivalent 20s. for the same amount of light from an Argand burner. On the other hand, he admits that the prime cost of the gas plant for providing the same amount of light to the same district would not amount to more than £80,000, as against £177,000 for electricity; and hence that, supposing the two systems to be equally efficient, the annual interest on the former would be a large advantage on the side of gas in the matter of prime cost, and a large advantage on the side of electricity in the matter of annual maintenance. He further admits, however, that none of the figures cited can be safely regarded as a panacea for the various requirements of things; and that in the face of the improvements, both in the manufacture of gas and in the use of electricity, which every day may be expected to bring forth, it is hardly possible to say more than lay down them. The data and calculations embodied in the paper are such as to render it eminently deserving of the most serious consideration of those interested in the subject, while the opinions and conclusions of so eminent an authority as Dr. Siemens on the above electrical topic will command attention.

Underground Conduits for Electric Wires.—

Letters Patent have also been granted to Mr. A. J. Boult (acting for Mr. J. D. Tiemar, of New York) in respect of an invention relating to underground conduits for electric wires. The conduit is made of baked pottery clay, or other suitable material, and is in two or more longitudinal sections, which are fitted to end, and secured together by Portland cement. Each longitudinal section consists of an upper and lower half, the latter of which is trough-shaped, with one or more compartments for the reception of the wires. The edges of the trough to which they are affixed are formed with lips, so that each section of trough and lid fits into the next section by means of over and underlying lappets which are made fast with cement or by cement. Pulling notches are formed on one or both sides of the covers, or of the trough, to facilitate their separation when required. At certain intervals along the conduit elbow bits are introduced for the purpose of keeping the wires.

Electric Incandescent Lighting and Apparatus.—

We are informed that a special engraving of an incandescent lamp in respect of which Messrs. Paterson & Cooper have recently obtained provisional protection, with a few carbon filament of high resistance placed in a glass bulb from which the air has been exhausted, the ends of the said carbon filament being connected with platinum or other wire, leading to the terminals of the lamp, through which the electric current is conveyed to the carbon filament. Speaking of the disadvantages of the present incandescent lamps, Messrs. Paterson & Cooper state:—"The production of the vacuum in the bulb is a difficult matter, and causes the greatest part of the cost of the lamps used in the manufacture of these lamps. Moreover, an absolute or perfect vacuum cannot be obtained therein. A further disadvantage attending the use of carbon filament is the smallness of the amount of light which can be obtained therefrom, as it cannot in practice be raised to true incandescence or a white heat because of the volatilisation of the carbon which would occur at such a high temperature. And the intensity of the electric current employed for the production of the light must, therefore, always be comparatively present and to the endurance of the lamp, but not by no means satisfactory, as the lamp will be very quickly destroyed by any slight increase of the current. By this present such lamps cannot be worked in series, as the extinction of one lamp will break the circuit, and all other lamps in the same circuit will be extinguished at the same time." All of these difficulties Mr. Werdermann claims to have overcome in his improved lamp, which is constructed as shown in the accompanying drawing. Fig. 1 represents one form of lamp, in which *a* is the carbon pencil as it is kept in contact with a carbon of metal electrode of larger cross sectional area *b*, by means of a spring *c* or other equivalent device, or other suitable liquid, to prevent the combustion of the carbon pencil between the drained distance, upon the end of the latter a collar *e* of asbestos or magnesia, in such a way that the pencil can be conveniently and economically renewed by a single "installation." He selects St. James's Square as a type of such an area, and supposes that the central establishment should be situated in the open portion of Trafalgar-square. Proceeding on a density of occupation of the above nature, which would be required, of the number of lights the necessary conductors, of the cost of the engines and dynamos, of the expense of laying the conductors, and of sinking the mains, the author arrives at the conclusion that the annual cost of a sixteen-candle incandescent lamp would be just below 22s., its equivalent 20s. for the same amount of light from an Argand burner. On the other hand, he admits that the prime cost of the gas plant for providing the same amount of light to the same district would not amount to more than £80,000, as against £177,000 for electricity; and hence that, supposing the two systems to be equally efficient, the annual interest on the former would be a large advantage on the side of gas in the matter of prime cost, and a large advantage on the side of electricity in the matter of annual maintenance. He further admits, however, that none of the figures cited can be safely regarded as a panacea for the various requirements of things; and that in the face of the improvements, both in the manufacture of gas and in the use of electricity, which every day may be expected to bring forth, it is hardly possible to say more than lay down them. The data and calculations embodied in the paper are such as to render it eminently deserving of the most serious consideration of those interested in the subject, while the opinions and conclusions of so eminent an authority as Dr. Siemens on the above electrical topic will command attention.

Metropolitan, Oct. 82.

The Dangers of Electric Lighting.—The very pro-

fessional letter of Mr. Montague Hemming, Asst. of the Phœnix Fire Office, published in the *Times* a few days ago, should go far to remove any misgivings in the public mind as to the supposed danger of the electric light. In the course of the past three or four years, during which period this new means of illumination has been brought more prominently under the notice of the public, several fires and accidents have been reported from various parts said to have been caused by some employed for electric lighting purposes, and many persons, not practically acquainted with the subject, were not unnaturally impressed with the idea that any such use of electricity was necessarily attended with some danger. In certain quarters, and for obvious reasons, this idea was fostered and encouraged by every possible means, and the opposition were considerably helped by the announcements that were issued by some of the insurance offices as to the conditions under which they were prepared to accept what were described as electric lighting risks. Experience, however, has demonstrated that with ordinary precautions certainly no more danger is to be apprehended from the employment of electricity than from gas, and the nature of the precautions stated in Mr. Hemphy's letter to be necessary in order to reduce to a minimum the risk of life are typical of the facility with which all danger may be provided against. Indeed, some of the safeguards, suggested form just and parcel of more than one of the Home Insurance terms of electric lighting. But the concluding paragraph of Mr. Hemphy's communication will, perhaps, be deemed the most reassuring. After alluding in highly commendatory terms to the care taken to prevent fires by some of the electrical companies, he observes :—"In order to prevent any unnecessary alarm in the mind of the public, I may state that all my experience so far has not caused me to alter in any way the opinions contained in my former report, viz.:—That where systematic and proper precautions are taken there is less danger from electric lighting than from gas." My very fairly be trusted to look after their own interests, and when the confidential adviser of such an undertaking as the *Phœnix* publicly expresses himself in language so decided as to the safety of the new illuminant, if only employed under proper conditions, the public will be well able to estimate for themselves the value of any statements issued by interested parties to the contrary.

Electric Lighting in London.—We are informed that the Metropolitan (Brush) Electric Light and Power Company have sent notices under the Electric Lighting Act of last Session to every local authority within the Metropolitan Postal District, intimating their intention to apply to the Board of Trade for provisional orders to authorise them to supply electricity for public and private purposes.

Electric Lighting Conferences.—In consequence of communications having been received from various parties, light companies intimating their intention to apply for provisional orders to enable them to supply the electricity in the various districts in South London, the Vestry of Camberwell have just issued invitations for a conference of South London Vestries to be held in the Vestry Hall, Peckham-road, on Tuesday, the 31st inst.

Electric Lighting at Chiswick.—Mr. Woodhouse and Chiswick.—It will not be long before the electric light makes its appearance in most of the London suburbs. A deputation (Mr. Woodhouse and Mr. Rawlinson on the Solway Court Estate at Richmond are to be electrically illuminated, and the arrangements for carrying out the same will be settled in the same way. Bedford Park, in the neighbouring parish of Chiswick, will also be electrically lighted shortly.—*Local.*

The Vestry of St. George, Hanover-square, and the Electric Lighting Act.—At a meeting of the Vestry of St. George, Hanover-square, the Parliamentary Committee presented a report, recommending that the Vestry should apply to the local authority (in this case the Vestry) themselves to apply for a Provisional Order for enabling themselves of the Electric Lighting Act; and that application be made accordingly.—Mr. Lewis Berry moved the adoption of the report. He contended that it was necessary for the Vestry to act, so as to protect themselves and prevent companies obtaining powers very similar to those now exercisable by gas and water companies.—Mr. Lewis seconded, feeling that the Vestry should have the power in their own hands, if they did this they could make their own terms and enter into a contract with a company or companies to supply electricity; or the Vestry could take the whole matter into their own hands.—Mr. Jones said that as a member of the Parliamentary Committee he at first supported the adoption of the majority, which had been recommended to the Vestry. He had, however, seen reason to alter his opinion, for if the Vestry applied they would be landed in a large initiatory expense, and if they did not carry out all the restrictions of the Board of Trade they were liable to severe penalties. If he obtained the order they were bound to act, because they asked for it, and on the cessation of abuse. He moved as an amendment that the report be postponed.—Dr. Schidlof, stated that if the Vestry intended to apply for a provisional order it would be necessary to have a special meeting of the Vestry for that day month, and to consider what conditions would have to be instructed to do a lot of preliminary business.—The Clerk read a valuable report upon the subject from the pen of Sellon, and the rev. chairman said he did not think the Vestry could do better than follow the suggestion contained in the report—that was to oppose the companies and remain quiescent for the present. He suggested that the subject should be referred back to the Parliamentary Committee.—Mr. Lewis said that if a local authority desired a licence, it was not absolutely necessary that they should act upon it. They might remain perfectly passive. Under the 12th section of the Act it was not necessary that the local authority should carry into effect the lighting of the parish by electricity, but they might depute it to any company they might think proper to do it, to reply to a question, said that unless the Vestry resolved that day to apply for a provisional order, their opposition to the bill would be of no use.—Mr. Jones said he did not think they could not delegate their powers to any company unless with the consent of the Board of Trade.—The amendment was lost by 14 to 12.—The motion was then agreed to by 23 to 13.—It was resolved to hold the necessary special meeting of the Board on Wednesday, the 20th prox., and that the solicitor be instructed at once to take the necessary steps.

Dr. Siemens on Electric Lighting.—We exceed-

ingly regret that the exigencies of space render it altogether impossible for us to publish at any length to-day the very interesting and instructive address delivered by Dr. C. W. Siemens at the Society of Arts, on Monday evening, on the subject of electric lighting, but its general features may perhaps be briefly stated. After an opening allusion to the general principles which govern electric lighting, Dr. Siemens gives precise data for the belief that the establishment of electric lighting over the towns of Great Britain and Ireland would absorb a capital of £800,000,000 sterling; but that the manufacturing appliances required in order to produce work representing this value of machinery and, of what must necessarily be the result of many years of technical development. On these grounds alone, he believes that the ambition of the various electric lighting companies is in excess of their powers of performance; and that for some time to come they must be regarded rather as specu lative than as practical undertakings. He did not afford any information as to the scope for improvement which may exist in arc regulators and in the manufacture of carbons for incandescence; but he stated that the existing dynamo machines restore, in the form of electricity, ninety per cent. of the power expended in working them, and also that they will again restore ninety per cent. of the first energy in the form of motive power derived from the electricity. On the question of the probable cost of setting up a system of electric lighting, Dr. Siemens, who previously had been content to state his opinion, has now taken the opportunity afforded by his address to state the data on which it is founded, and thus to render it far more open to criticism than before. He believes that his conversion to a quarter of a square mile, densely populated, is as large an area as can be conveniently and economically covered by a single "installation." He selects St. James's Square as a type of such an area, and supposes that the central establishment should be situated in the open portion of Trafalgar-square. Proceeding on a density of occupation of the above nature, which would be required, of the number of lights the necessary conductors, of the cost of the engines and dynamos, of the expense of laying the conductors, and of sinking the mains, the author arrives at the conclusion that the annual cost of a sixteen-candle incandescent lamp would be just below 22s., its equivalent 20s. for the same amount of light from an Argand burner. On the other hand, he admits that the prime cost of the gas plant for providing the same amount of light to the same district would not amount to more than £80,000, as against £177,000 for electricity; and hence that, supposing the two systems to be equally efficient, the annual interest on the former would be a large advantage on the side of gas in the matter of prime cost, and a large advantage on the side of electricity in the matter of annual maintenance. He further admits, however, that none of the figures cited can be safely regarded as a panacea for the various requirements of things; and that in the face of the improvements, both in the manufacture of gas and in the use of electricity, which every day may be expected to bring forth, it is hardly possible to say more than lay down them. The data and calculations embodied in the paper are such as to render it eminently deserving of the most serious consideration of those interested in the subject, while the opinions and conclusions of so eminent an authority as Dr. Siemens on the above electrical topic will command attention.

Underground Conduits for Electric Wires.—

Letters Patent have also been granted to Mr. A. J. Boult (acting for Mr. J. D. Tiemar, of New York) in respect of an invention relating to underground conduits for electric wires. The conduit is made of baked pottery clay, or other suitable material, and is in two or more longitudinal sections, which are fitted to end, and secured together by Portland cement. Each longitudinal section consists of an upper and lower half, the latter of which is trough-shaped, with one or more compartments for the reception of the wires. The edges of the trough to which they are affixed are formed with lips, so that each section of trough and lid fits into the next section by means of over and underlying lappets which are made fast with cement or by cement. Pulling notches are formed on one or both sides of the covers, or of the trough, to facilitate their separation when required. At certain intervals along the conduit elbow bits are introduced for the purpose of keeping the wires.

Electric Incandescent Lighting and Apparatus.—

We are informed that a special engraving of an incandescent lamp in respect of which Messrs. Paterson & Cooper have recently obtained provisional protection, with a few carbon filament of high resistance placed in a glass bulb from which the air has been exhausted, the ends of the said carbon filament being connected with platinum or other wire, leading to the terminals of the lamp, through which the electric current is conveyed to the carbon filament. Speaking of the disadvantages of the present incandescent lamps, Messrs. Paterson & Cooper state:—"The production of the vacuum in the bulb is a difficult matter, and causes the greatest part of the cost of the lamps used in the manufacture of these lamps. Moreover, an absolute or perfect vacuum cannot be obtained therein. A further disadvantage attending the use of carbon filament is the smallness of the amount of light which can be obtained therefrom, as it cannot in practice be raised to true incandescence or a white heat because of the volatilisation of the carbon which would occur at such a high temperature. And the intensity of the electric current employed for the production of the light must, therefore, always be comparatively present and to the endurance of the lamp, but not by no means satisfactory, as the lamp will be very quickly destroyed by any slight increase of the current. By this present such lamps cannot be worked in series, as the extinction of one lamp will break the circuit, and all other lamps in the same circuit will be extinguished at the same time." All of these difficulties Mr. Werdermann claims to have overcome in his improved lamp, which is constructed as shown in the accompanying drawing. Fig. 1 represents one form of lamp, in which *a* is the carbon pencil as it is kept in contact with a carbon of metal electrode of larger cross sectional area *b*, by means of a spring *c* or other equivalent device, or other suitable liquid, to prevent the combustion of the carbon pencil between the drained distance, upon the end of the latter a collar *e* of asbestos or magnesia, in such a way that the pencil can be conveniently and economically renewed by a single "in-

The Metropolitan, (London,) Oct. 82.

Gas Making in Paris.—The Gas Company of Paris are now laying in the principal streets of central Paris new gas mains, one meter in diameter. The process is peculiar, for the mains are composed entirely of sheet-iron tubes, which have been rolled in hot bitumen, mixed with fine gravel. When cold this covering is said to possess a very hard consistence, and protects the sheet-iron not only against deterioration, but against oxidation, even in the most humid soil.

The Cost of Electric Lighting.—We cut the following from an article, which appeared in the *Daily News* yesterday, on the cost of electric lighting :—

Without pretending to have plitched upon the very best system, we may confidently assert that the cost of estimate for supplying light by the new Pernnyl process is far from being the worst. If quiet can supply the light more cheaply, so much the better; but the following estimate for "house-to-house" lighting by the process named compares favourably with all others.

Estimate for electric lighting by Pernnyl system, with 2,000 incandescent lamps, each of one-candle power :

I.—Preliminary outlay—	
1. Dynamo machines	£1,200 0 0
2,000 lamps at 5s. each	500 0 0
2,000 sockets	100 0 0
Switches	25 0 0
Indicators	8 16 0
Fixing, packing, starting, &c.	300 0 0
Installation	25 0 0
Laying mains, and wire	£2,158 16 0
Station and machinery house	1,000 0 0
Engine of 200-horse power	500 0 0
Insulators, &c.	50 0 0
Total capital outlay	£3,708 16 0
2.—Annual cost—	
10 per cent. of this total for interest and depreciation	£370 17 0
Salaries of engineer and assistant	400 0 0
Engine fuel, 3lb. per horse-power per hour's work	150 0 0
Lamp renewals	100 0 0
Sundries	1,000 0 0
	25 7 0
Total cost per annum	£2,050 0 0

There is nothing so familiar as gas to take as a basis of comparison, and we may proceed to place this annual cost of £2,050 for the illumination. Reckoning the week at 25 hours, and giving the same per diem for each week, it appears that the 2,000 lamps five hours would require the consumption of 250,000 cubic feet of gas per week. At 3s. per thousand cubic feet, this would cost 37s. 6d. of sheet gas per week, or about £2,500 per annum, which is not as much as the cost of electricity is above specified. Hence, if gas is taken at its actual price, and the Pernnyl estimate of cost, cost to the Corporation, without address for officials, collection, and so forth. The electric light, nevertheless, gives an idea of economy can be done in the way of producing artificial light on a large scale. Were we to detail the estimate for the electric light on a large scale, few items, say 100 instead of 2,000, would be saved, for it is a rapidly diverging item. It is, on the other hand, the estimate would be additionally in favour of the new electric light were many more lamps served from a single source. If, indeed, we suppose that the total cost of popular electric light to be supplied hardly-paid out that the same as large as those which are now in use, when it is supposed to be, Until the gasometric principle is now light from a single station, the dynamo representing the central work in both cases (called "prime"), a fair understanding of the matter in the case of the electric light, but there will be difficulty to arrive at.

The Statist, May 19, 1883.

Electric "Sun" Lamp and Power Company.—The issue of £20,333 which has been paid up upon the 7,000 shares subscribed for by the public in this company has not proved sufficient to enable the Board to complete the central station at South Kensington, the Grosvenor Gallery, and Regent-street, which is being carried on by the Edison Electric Light Company. The Board, however, have decided to issue the remaining 3,000 shares at par, and the result is that the whole of the capital has been fully satisfied in issuing the company with ample capital for eight lamps on condition on the part of the Board to oblige the directors to hasten matters as far as possible. Of this the directors have called up £10,000, they had power to call £15,000 at their discretion, and they had also power to call £10,000 more if they should think it necessary. The directors have already been paid, £1,000 for their services, and they could compel the vendors to take shares to the amount of £5,000 in cash or shares. If not paid in cash by the vendors, they could compel the vendors to take shares. The Board have, however, shown them such liberality that they apprehended no difficulty from them.

Metropolitan, May 19, 83.

Opening of the Electrical Exhibition in Vienna.—The International Electrical Exhibition in the Rotunda at Vienna was opened on Thursday by the Crown Prince Rudolph, who was accompanied by the Count of Flanders, the Prince of Portugal, the Emperor's cousins, Philip and Albert, and many foreign and local princes. Although in the scientific section there was not much to see in broad daylight, a number of lamps had been lighted in it to show the manner in which the basement and the various rooms showing the applications of the electric light in household uses were prettily illuminated. Besides scientific displays, dining-rooms and bedrooms, there is a kitchen with an Electric range and oven, and a boiler-house, in which the engine represents a deep blue sky, upon which electric lamps shine as the stars, and where, by the way, Turkish pastilles are to be manufactured. Numerous features. The theatre, with its fover, dressing-rooms, and auditorium, is large enough for any provincial town. Opposite the stage is a box containing apparatus for producing any so-dead effect of lightning on the stage. The princes gallery are brilliantly lighted by three arc lights. O the pavilions in the Rotunda the finest are those of Siemens & Halske and Trenchi, with a complete collection of all the telegraphic apparatus in use, and a large plan of the telegraph system of Paris. The English fog warns have a very unsatisfactory exhibition. There is little beyond the simplest telegraphic instruments, and those not many of these. In the machine department there are fine specimens of dynamo-electric machines of every kind; and the Gramme dynamo for lighting purposes. Gaiu's enlosed machine, which combines a steam engine and a dynamo in one, is regarded as very powerful. The exhibition will not be opened at night until the 20th, when it is hoped all will be in readiness.

Metropolitan, May 26, 83.

The Electric Light at the Reform Club.—An Edmundson and Vincent dynamo is used to drive twenty Swan lamps, lighting one bay of the kitchen, hall, and fifteen bedrooms. Twenty-four Swans have a ground glass bulbs, lighting one end of the dining-room. The lamps are fitted with Edmundson's perfect swallows, and have to be to perfection the beautiful designs of the carved and richly-gilded cornices, centres, and walls of these magnificent apartments. The usual illumination is by oil and paraffin lamps, so that the contrast is marked. The motive power is supplied by a table engine, which rests merely from the foundation of the club, and has long been in use for the purpose of pumping water from the Club's cistern well in favour of a modern horizontal engine.

The Sun Electric Lamp.—Last week we mentio above we described the Sun electric lamp, which was then introduced to public notice. Since that time several improvements have been made in the detail construction of the lamp, and the manufacture and application upon a practical scale have now been fairly entered upon. The Electric Sun Lamp and Power Company have established a factory at Bloomsbury Mansions, Edgingham-street, Regent-street, where a large party assembled on Friday evening to inspect the works and the various processes of manufacture. The visitors were received by the chairman of the company, Mr. J. A. Berly, C.E., the engineer to the company.

The Australian Electric Light Company have extended its operations to North Melbourne and other suburbs of the Victorian metropolis. Two of the Brush-control arrangements, in addition to the Opera House and several shops, are now being worked by the company, and other contracts are in course of execution.

The Statist, (London,) May 26, 83.

Electric Sun Lamp and Power Company.—A general meeting of the shareholders of this company was held on Wednesday, when the chairman stated that the directors had been proceeding to distribute had previously decided with the committee of allotment had been fulfilled, and would justify operations which were at that time and which were now before them. He the licensee they had been fully fortified in launching the company with ample capital for eight lamps on conditions on the part of the Board to oblige the directors to hasten matters as far as possible. Of this the directors have called up £10,000, they had power to call £15,000 at their discretion, and they had also power to call £10,000 more if they should think it necessary. The directors have already been paid, £1,000 for their services, and they could compel the vendors to take shares to the amount of £5,000 in cash or shares. If not paid in cash by the vendors, they could compel the vendors to take shares. The Board have, however, shown them such liberality that they apprehended no difficulty from them.

Metropolitan, June 2, 83.

The Newington Vestry and Electric Lighting.—An estimate has been furnished to the Vestry of Newington by the Electric Carbon Carbrge and Apparatus Manufacturing Company of Scotland of the cost of the electric lighting installation. Commencing at the Angel, and although it does not so appear from the figures before us, we presume the company are prepared to provide the plant and carry on the lighting for the amounts stated. The estimate is for an installation, at Angel-corner, of 16-candle power and 50 incandescent lamps of 50-candle power each, giving a total candle power of 28,800 candles. The initial cost of the whole plant is estimated by the company at £10,140, and the annual cost of maintenance at £4,656. The reason, assuming that electricity was charged for at the same rate as gas, and assuming also only 5,000 lamps to be in constant use, is stated at £4,177 per annum, showing an excess of receipts over expenditure of £521, which would enable the loan for the plant to be paid off within 15 years. The Vestry's own estimate of the first cost of the installation was £20,000, and the annual receipts showed an excess over the expenditure of only £83.

Electric Lighting at the Fisheries Exhibition.—Some particulars have already appeared in these columns of the arrangements for the electrical illumination of the Fisheries Exhibition at South Kensington, and although we can tell the story before the lighting approaches completeness, there is no uncertainty that it will ultimately form one of the most extended and most interesting shows of the kind. Most of the well-established systems are amply represented, while on the other hand there is a total absence of unknown names from the list of exhibitors. The fashion which distinguishes this show from previous ones is, that instead of the various systems being massed in a large hall, where the effect of the whole was blended into one great glare of light, each will have its own special building, and can be there disposed in the best way to show off its special advantages. The exhibition is so extensive that this is readily possible, without sinking the mass afforded to each, while the great diversity in the form and dimensions of the building renders it easily possible to find suitable accommodation for the display of all sizes and varieties of lights. The main ventilate is to be illuminated by 500 incandescent lamps supplied by Messrs. Woodhouse and Rawson, and by Mr. Maxim. Elvinstone and Vincent from two of their dynamos. At the end of the vestibule, where a short flight of steps leads into the British Sea Fisheries Section, will be seen the magnificent exhibit of Messrs. Siemens Brothers, with their Swan lamps will be displayed upon the underside of the principals of a roof 600 ft. long. Messrs. Siemens Brothers also exhibit their dynamo machines, of which each of the two principal varieties, which were supplied in parallel circuit instead of in series as has hitherto been the case, will be employed being at the Alexandra Palace, and being most without any modification whatever. The range of refreshment rooms to the left of the fine gallery will be lighted by twenty-eight Lever are lamps, fed by two Ditgin and two Gramme dynamos. The passage leading to the right, past the shelter and the Palace of Water Pavilion, is to be occupied by Mr. Mattheson, whose lamp has lately been established at the Aquarium, where it was severely handicapped by the insufficient supply of steam. Branching from this passage to the left, the machinery will be running which will be illuminated by 85 Gulcher lamps, arranged parallel, and to the right the Edmundson and Vincent lamps will be supplied by the Electrical Power and Light Contract Agency by six Westinghouse dynamos of the same pattern as those at present in the promenade gallery, in which will be found the only striking specimen of the Anglo-American Brush Company's system. Mr. Mr. Edmunds, who further provides 500 incandescent lights in the western gallery, and 500 in the Conservatory, and on the upper terrace a light is to be seen at work, as also in Middle-square, where 20 hanging arc large lamps of 2,000 candle-power each, and 100 incandescent lamps, will illuminate the usual resort of the concerts of three owners in the States, and will be seen at work for the first time in this country. The Crystal Palace Company, which intends the garden at the side nearest Queen's-road, to be lighted by electricity, will probably be supplied by Messrs. Siemens Brothers dynamos, while the adjoining building will be supplied with eight arc lamps of the same pattern as those in the Conservatory in addition to the installation we have already mentioned, will have twelve lamps in the Spanish section, and four Crookes lamps in the building, in which are included the countries of the Eastern Pacific. The almost concludes the list, and we have only to note twelve Gerard lamps in the Russian Section, seven Lea lamps in the Fish Market, and two Hawkes lamps at the entrance to complete the catalogue, as far as it is at present determined. Messrs. Crosfield and Orlikd are to have twelve stations for the demonstration of their method of distribution by secondary generators, but at present their situation and extent are not fixed. There has been a great deal of holding back among the exhibitors to see what their competitors would do, with the result that the whole installation is behindhand.

Metropolitan, May 19, 83.

Electric Lighting in London.—The St. George's Vestry (Hanover-square) agreed, at their meeting on Thursday, to the application of two companies—the Swan Electric Lighting Company and the Metropolitan Electric Supply Company—for the use of the streets for the purpose of electric lighting. The committee appointed to consider the scheme (of which Sir Arthur Blomfield is the chairman) reported that the difficulty which had arisen with the Swan Company as to the indemnity had been overcome. They were also to state that the Metropolitan Company had made no applications for a fresh area (as shown on a plan, dated 9th May, by the clerk of the parish) to the west of Bond-street, to Park-lane, including Piccadilly, and down to the parish bound in St. James's-street; the applications being for a portion of Old Bond-street and the whole of Piccadilly within the area; portion of the latter to be lighted by the same system of electricity as that in parallel to the west of Berkeley-square. The amount necessary for the whole area of schedule A is estimated at £8,000, to cover all expenses, and of this the company will give security for £4,000 (50 per cent.).—Mr. Livingston, the surveyor, states that the Swan Company propose to light all the portions of the parish in the in-wards part of Grosvenor-square or Piccadilly, and from the south of Berkeley-square to Cubitt-street, Belgrave. Along the Hanover-square district, the company also included in their Schedules A and B the whole of the out-wards south of Berkeley-square, with the exception of a small portion between Lupus-street and Vincent-square, and that in the district about Victoria-station.—The report was adopted, and the clerks of Sir Arthur Blomfield were employed.

Miscellanea.—The new premises recently fitted up for the office of the *Pall Mall Gazette* in Westminster-street, Dublin, are to be lighted throughout on the incandescent system of electric lighting. The installation is to be erected by Messrs. Simmons, and will consist of 150 Swan lamps.

The Steamship *Tallyman*, belonging to the Union Company of New Zealand, is to be fitted throughout with incandescent lighting on the Swan system. This makes the fifth vessel belonging to the company electrically lighted; of the four previously fitted two are on the Aorangi and two on the Swan system.

Electric Light and Power Generator.—The report of the Board of Trade into the accident which befell the Maxim and Maxim systems of electric lighting; that the Maxim incandescent lamp had proved under experience all that the directors anticipated from it, in beauty, durability, and economy, while the Weston dynamo shows Mr. Crosbee, which were supplied to form a portion of the whole purchase under which only the Maxim patents for the dynamo and lamps could be secured, had, after thorough the practical tests, been proved to be equally satisfactory. In moving that the report be received, the chairman entered into a history of the company which was originally established for the purpose of working the Lontin patents, but the success of the Maxim had induced them to purchase the Weston and Maxim patents. The price asked for them was £100,000, but they succeeded in obtaining them for £70,000. The report stated that the advantages which had accrued to other companies from the arrangements they had at this moment thrown on their hands, and brought to might say that something like £500,000 would be saved to the company in a short time from these. Mr. Crosbee, their consulting electrician, had lately become a director of a new company which had secured a lamp, an invention of his. That lamp was offered to this company, but they were advised not to purchase it until they had had opportunities for testing its powers of endurance, and these opportunities were not afforded. They had been expecting his resignation. He was receiving from them a salary of £250 a year, and was engaged to them for two years. They proposed to establish small local companies, with or without convenience, as opportunities occurred, who would pay them a royalty for their patents. On the motion of the chairman of the company, the name was changed to "The Maxim-Weston Electric Company (Limited)."

Chelsea and the Electric Lighting Question.

This question was considered at the meeting of the Chelsea Vestry on Tuesday, amongst the members present being Sir Charles Dilke, M.P., Mr. Firth, Colonel Beach, and the Hon. Colonel Dillon. The Vestry had under consideration the notice received from several electric lighting companies of their intention to apply for provisional orders for the district, together with an electronic report upon the whole subject by Mr. H. D. Harper, C.E., their surveyor. The report dealt fully with the recent progress in electric lighting, the Electric Lighting Act, the Board of Trade rules, the cost of the various plants, and suggested regulations and conditions. Mr. Stayton submitted a draft of a memorial in satisfaction for Chelsea, and a draft of a limited but more practical installation at £5,000: but before any one type of the supply of electricity for the district was fixed upon there ought to be some, even if all the Electric Companies in the district were applied to, of course, very doubtful. Mr. Stayton considers that local authorities would act wisely in pausing before committing themselves to a license or provisional order, because the first author is necessarily successful, and the financial risks and legal liabilities involved thereby are great to be undertaken by a public body. The report concluded with the following recommendations, which were unanimously adopted:—1. That at present it is not desirable for the Vestry to apply for a license or provisional order. 2. That the Vestry are not averse to any application for a license until the draft shall have been submitted to, and has received the approval of, the Vestry. 3. That it is desirable to oppose the application of any such, who may appear most likely to carry out the undertaking in a satisfactory manner, and who will agree to such of the suggested conditions as the Board of Trade may approve, and that the Electric Lighting Committee and the surveyor be empowered to confer with the promoters of any such with that object. 4. That the solicitor be instructed in drafting the progress of the application for provisional orders, and to take all necessary steps to oppose the same until satisfactory conditions are obtained.

The Newington Vestry and the Electric Light.

A memorial, signed by a number of ratepayers of St. Mary, Newington, was held on Tuesday evening at the Lecture Hall, Caterham-road, Walworth, against the proposal to apply to the Board of Trade by the Newington Vestry for a license for the supply of electricity. The Newington Vestry for a license for the supply of electricity. The Newington Vestry for a license for the supply of electricity. The

Metropolitan, Sat. 28, 82

Electric Lighting at Birmingham.—The Gas Committee of the Birmingham Town Council have prepared an elaborate report on the relative advantages of gas and electricity, with special reference to the applications for lighting powers, of which notice has been given by various companies and persons. The committee, after full and careful consideration of the subject, recommend—1. That no application be now made by the council for authority to supply electricity in the borough or in any part of it. 2. That the council be authorised to oppose any application under the Electric Lighting Act or by special Act of Parliament. 3. That the committee be authorised to enter on negotiations with the companies applying for powers to supply electricity within the borough for the purpose of arriving at some terms or some sufficient provision for the protection of the council of the full control of the streets, for the adoption of suitable plans for the works, for the safety of the public, and for the inspection of the installations within a limited time, and for the limitation of the duration of the concession. 4. That, subject to satisfactory conditions being arranged with the companies in this way, the committee be authorised to support on behalf of the council such applications to the Board of Trade by one or more of the companies for powers to supply one or more limited areas within the borough. 5. That, subject to the foregoing recommendations, the committee be authorised to oppose all or any of the applications of which notice has been given to the council.

The Chelsea Vestry and the Electric Light.—A special meeting of the Chelsea Vestry, convened under the powers of Sec. 3 of the Electric Lighting Act, was held at the Chelsea Vestry Hall on Wednesday, Mr. Tuxbridge in the chair. Mr. Odgers explained that "it is incumbent on the vestry at this time to take any action with respect to an application for a Provisional Order for electricity in this parish." The Vestry had, since the issue of the notice calling the meeting a month since, appointed a committee to make a thorough investigation of the subject; but their work was not nearly complete, and it would be premature to proceed in the matter without further information before them.—Mr. Hodge seconded, and in the course of an exhaustive review of the Vestry's position, pointed out the principal obstacles in the way of the Vestry adopting the electric light, referring especially to the difficulties in obtaining a site for the works, and to the cost. £100,000 would, at a low estimate, be the expenditure involved in placing the mains, so the very largest capital sum would be obtained for the undertaking. If such an intention were made the Vestry would find either that it would be placed at a great disadvantage, or that it would have to employ as near as might be to make it profitable. The Vestry must be prepared to sell a dividend of £7,000 on a capital of £140,000. He found that the annual cost of maintaining the Siemens lights in the Strand, Embankment, and Gardens, Chelsea, being into account the payments of the parish at £6,000, and the number of inhabited houses at 20,000. The inhabitants of the Vestry's offices and staff, and the Vestry would be called upon to pay £7,000 a year as the annual necessity for the expenses. The Vestry ought not, therefore, to pledge themselves to such an expenditure, but offer to a trustworthy company every possible facility, since the Vestry would be able to supply the light well in hand by the end of the year. It must not be expected that the Board of Trade would allow a local authority to sell their private property to its private use, or refuse it to any company that came on the terms. The meeting was put and carried unanimously, the Chairman remarking that it was at present the only subject under consideration. The question could be reopened, and a second special meeting convened, as the necessity arose. The committee had been able to procure the report of the Islington Vestry upon the subject, which they were now making.

The Islington Vestry and Electric Lighting.—At the last meeting of the Islington Vestry the consideration of the report of the Lighting Committee upon the application of Messrs. Siemens for a Provisional Order (the substance of which was overwise, it will be remembered, to the effect that the Vestry appeared disposed to give a final opinion as to the desirability of adopting the electric light, and to recommend the Board to grant the application in itself, it was considered that, effective as such a light in the streets, in its infancy, and unverified, as a means of lighting of the system, which time would probably remedy. The committee recommended that the report be referred back to them with authority to take the necessary steps. It was moved that the report be adopted, which was seconded by Mr. Stevens.—Mr. Moss said there was nothing whatever, with one exception, to recommend to have calculations made of the probable cost of the service, and a bulk of paper. He (Mr. Moss) could not see the purpose of making a way to get the electricity, an experiment to see where it was not a fair one. The lighting of private houses was the next consideration to the committee, but the committee seemed to think it was possible that in the investigations part of the report. They had been lighting of public authorities; and he (Mr. Moss) was most desirable that the local authorities should undertake the work and authority, which was the Vestry, then a public company.—Mr. Hall supplying the electric light Vestry, he thought, be adopted only so far as the Vestry take steps to oppose the granting of a license or provisional order to any other person or public company to supply electricity in the parish.—Mr. Thompson seconded the amendment.—Mr. Lambert considered it a great mistake to have referred the subject to the Lighting Committee, it should have been a special committee. The committee had gone nowhere but the Board of Trade to make inquiries, and had elected a very short time to the matter, the work being only about the last of Mr. Parry and Mr. Dyson.—Mr. Newman believed that the question had not received the consideration it had from the hands of the committee.—Mr. Price said the Lighting Committee had been blamed for not doing more than they had done, but they had not been told what they would have gone further in the matter.—Mr. Bloomfield. Electric lighting was in its infancy at present, and no doubt improvements and experiments, and he was opposed to the adoption of the electric light until it was a commercial success. After some further remarks had been made, the amendment on Dr. Chilcott was put and carried.—Mr. Foley then moved as an amendment, that the question be referred to a special committee for consideration, which was also seconded.—The further consideration of the matter was then adjourned till the next meeting.

The Financier, alluding to the "Brush" Electric Light Companies, states that several shareholders are threatening to move an injunction against the "parent Brush" for compensation and damages in selling exclusive rights for some patents to which, it is alleged, they have a valuable title.

The Corporation of Sheffield, having resolved to apply to Parliament under the Electric Lighting Act for extensive powers for the illumination of the borough by electricity, not only in the streets and public buildings, but also in the private houses, Mr. Crompton, C.E., of London, who has been specially consulting engineer to the Corporation, has been instructed to prepare and report upon a scheme to be adopted by the Corporation.

It having been stated that it is the intention of certain parties to lay down a system of distribution of electric force for lighting purposes, upon a plan consisting the use of secondary batteries as a means of storage and dynamo machines and transformers, Mr. St. George Lane Fox gives notice by public advertisement "that such a combination is covered by the Letters Patent granted to me on the 9th of October, 1878, and that any infringing or acting under patented combination without licence from me will be proceeded against."

Miscellaneous.—The Admiralty have decided to light the *Inconstant*, *Monarch* throughout with Swan's incandescent electric lamps. The Swans engineer is to be employed are of the Siemens's type, driven by a Brotherhood engine.

Metropolitan, Feb. 1884.

Metropolitan Brush Electric Light Company.—An extraordinary meeting of this company was held at the Cannon-street Hotel on Tuesday, under the presidency of Mr. Bower, to receive the report of the committee of investigation appointed to inquire into the affairs of the company. Mr. Alexander Peebles read and moved the adoption of the report of the committee, in which it was stated that no lighting stations had yet been established, no street recommended winding-up. This having been seconded, Mr. Shipp undertook to show how they could be made money out of.—Mr. Hammond made an effort to take money out of the company, giving £20,000 in debentures and £30,000 in fully-paid shares in the Anglo-Continental Company, or £20,000 cash.—Eventually the resolutions were passed adopting the report and resolving on winding-up.

Miscellaneous.—The Wellington Club hall-room, Liverpool, is now lighted by the electric light. More than two dozen lamps have been fixed in the cut-glass chandeliers with which the rooms are fitted, rendering a very beautiful effect.

Metropolitan (Chelsea) July 1882

The Pilsen Joel and Oriental Electric Light Company.—The first ordinary general meeting of the Pilsen, Joel, and Oriental Electric Light Company was held on Tuesday at the City Terminus Hotel, Cannon-street, Sir Lees in the chair. According to the directors' report, the meeting was convened in accordance with the terms of the agreement, which required that a general meeting of the shareholders should be held within four months of the registration of the company. This was the first opportunity they had of meeting, and the second was to form themselves into an extraordinary meeting after the general meeting was finished, for the purpose of considering certain changes in the articles of association which the formation of the Stock Exchange considered desirable in the interests of the shareholders. Although the present meeting was not one at which it was usual to enter into any detailed statements of the proceedings of the company, which the directors hoped to do at the next ordinary meeting, yet it was a pleasure, for the directors to meet the shareholders at any time and to give them any information in their power as to the operations of the company. The company was registered on the 19th of May, and was advertised on the next day, and such was the demand for shares that the new electric light company that in the afternoon of the 20th of May, the directors were obliged to advertise that no more applications for shares could be received after the 23th for town, and the 28th for the country. We might state that for 28,000 shares applied for they had to dispose of to the public they had applications for 168,000, and for a capital of £140,000 they had applications amounting to £1,400,000—more than seven times the number of shares they had to dispose of. The allotment was completed on the 23rd of May, and was to about 800 shareholders. The shares which were issued were of the value of £5, and the directors had contemplated calling up the first £2, of which £1 per share, which would give a working capital of £2 per share, which had been called up, and with the exception of a trifling sum, all paid up. The shares were allotted pro rata to the applications, and the allotment is considerable premium. But before the company was actually formed and in operation, the directors had to take a very different view of its prospects than when it had first been started. When the company was first created, the directors had hoped to be able to sell a number of concessions in order to form a number of smaller companies, as had been done in the case of Belgium. But from the moment of the existence of the company, it was pretty evident that the latter position was not to be the case, and that the continental working of the consolidated, and from the establishment of a successful and commercial manufactory of its valuable patents. After referring at length to detail matters, he said, in conclusion, that the object of the directors had been throughout to insure a substantial and profitable consolidation of their several patents, to study strict economy in their arrangements to avoid all expensive agencies, to refrain from costly and unnecessary solicitations, and so to conduct the operations of the company that the public, as they were confident of realising, an ample and just satisfactory return for the shareholders for the money which they had invested. Several shareholders expressed themselves in a satisfactory manner with the statement made by the chairman, and the meeting was then resolved itself into that of the purpose of adopting various formal alterations in the articles of association of the company. These were all agreed to, and the proceedings terminated with a very hearty vote to the chairman.

ELECTRIC LIGHTS.

Owing to the pressure upon our columns, caused by the publication of the proceedings of the American Gas Light Association, the continuation of the article, by H. Mossday, on the "Value of Electric Units," is unavoidably delayed.

Electric Lighting in Chesterfield, England.

A late Number of *Engineering* contains this paragraph relative to the attempted electric lighting scheme at Chesterfield, England:—

"The experiment of lighting by electricity at Chesterfield has not so far proved successful. It will be remembered that about a year ago, owing to differences with the gas company, the Corporation determined to abandon the street lighting, and to illuminate all the streets with arc lamps. The contract was entrusted to the Hammond Company, and it was decided to use both arc and incandescent lamps. After a long delay the work has recently been handed over by the contractors as incomplete, but according to the Town Council it is little less than a dismal failure. "In a letter addressed to the Mayor by the Brush Company are most variable in their lighting power, whilst some are good, others only give a feeble light, instead of a light equal to that of fifteen candles as expected. The arc lights are doing good service in some of the large streets, but on a whole I think it has been fully demonstrated in a year's trial if Chesterfield, that the field for arc lighting is very limited indeed.' The inhabitants of the town do not appear inclined in any single instance to abandon gas, and the disappointment at the result of this enterprise is very great.

"Judging from the success that has attended the electric lighting of streets elsewhere we suspect that the fault lies chiefly with the mode of installation; the defective Lane-Fox lamps can doubtless be replaced by perfect ones, and probably a better distribution of the arc lamps could be effected. Although Gen's letter is a timely one, that no many municipal bodies are turning their attention ardently to the question of abandoning gas."

Electric Lights a Nuisance.—The blazing electric lights in the City Hall Park are nuisances. They dazzle the eyes, and thereby increase the peril of crossing the crowded streets that border the park. Where they do give no light they give too much, and at times they leave the park in darkness. The old gas lamps served the purpose much better, and made the park safer and more pleasant.—*N. Y. Sun.*

March 1882.

At the *Fête* in Paris yesterday the electric light played a prominent part. It was used to illuminate the fountains of the Tuileries Gardens, the upper portion of Notre Dame, the Louvre, the dome of the Pantheon, Porte Saint Denis, and several other public places. Among the electrical displays in the Palais de Glace the most interesting experiments was that of M. Serrin from the top of his house, facing the Place de la Bastille, where the gas companies organised an unrivalled illumination. M. Serrin has invented a system which has been already tried with great success, and may be moved in any direction with an amazing velocity. His powerful ray of light describes curves in azimuth and in distance. Some new forms of regulators were exhibited for the first time on this occasion. The *Fête*, being inclosed, was celebrated all over France in the 40,000 communes or townships of the Republic, and the electric light was used in the provinces as well as in Paris. The most notable display was probably at Rouen, where a group of sixteen Siemens lights, of a power of about 100,000 candles, was placed on the top of the spire of the Cathedral.

More about Mr. Edison and His System.

"ELECTRIC LIGHTING."

TO THE EDITOR OF THE TIMES.

SIR,—Having now before us most of the "objections" lodged in respect of the application for Provisional Orders made by our clients, the Metropolitan (Brush) Electric Light and Power Company (Limited), we are enabled to arrive at the conclusion that there are but few cases where the Board of Trade will not be able to adjust the differences between the local authorities and the undertakers.

The announced determination of the Board of Trade to give effect to the provisions of the Electric Lighting Act has prevented purely obstructive objections, and the undertakers have confidence that in the public interest the Board of Trade will settle the outstanding points, in what is necessarily more or less of a bargain, between the local authorities and the undertakers. So far as the objections are tenable, they are of a commercially trifling nature, and constitute the most conclusive testimony to the efficiency and ability with which our learned counsel, Mr. Fletcher Moulton, Q.C., constructed the plan of area for application, and carefully selected the salient legal and actuarial features. Mr. Monckton's temperate letter of the 30th instant may be taken as a fair sample of the views of the bulk of the metropolitan vestries—views which we are not likely to underrate to considerable modification; after more mature study of the subject, and when the safeguards to be introduced into the Orders are more fully specialized.

We could not suppose that the draft Order, even with the more backward of the proposals, would be regarded as perfect, but we are now convinced that if both parties attend the Board of Trade Inquiries with a wish fairly to meet each other, and to secure legislative powers which, while protecting the interests of the public, shall offer an adequate return to capitalists, a sound and satisfactory Order will be the result.

As to the clauses relating to public safety, efficient supply, and price, the Board of Trade will probably not be before them such skilled evidence as will enable them to correct any inequalities which may exist in a manner satisfactory to the vestries.

As to the breaking up of streets, if deemed desirable by the local authorities and the Board of Trade, the company would not object to the work being carried out at the fullest extent by the vestry. And as to the "overhead" wires, the company has given instructions to the heads of the Board of Trade.

Then, as to the compulsory portion of the work, it seems only reasonable that if a pioneer company incurs the risk of establishing a new enterprise and bears the expenditure of capital demonstrates the public utility of a new source of light, other things being equal, it should have the preference in carrying out the further work if required on the request thereto within the district. Nothing more than this is proposed by the Order. The question of the time into section, the first and most important of which the undertakers secure the obligation of lighting during the period of two years. In addition to the 200-horse power engines running at a high rate of speed, there were also attached to each a four-inch bobbin, which in effect increased the power equal to about 1000-horse. The next thing that happened was the melting in a second of six or eight pounds of copper which was thrown off in a sort of vapor, filling the room and everything else with the necessity of extinguishing all when any one was out of order was manifested by the failure of the lights, and moreover there was a possibility of the insulators connecting the wires with the ground having also been thoroughly demonstrated, and I have now no fear whatever of the perfect working success of the scheme. I have also perfected a meter for measuring the amount of electricity used in a given time, which is absolutely perfect and certain, because not mechanical, and therefore not liable to get out of order. Furthermore, the production and sale of electricity for lighting purposes will in no way come in competition with gas, as many more than gas does with kerosene, because it has an actual commercial value above gas, which will take it out of the line of competition and elevate it to a plane of its own. We measure electricity, for instance, on the basis of a ten-candle power of illumination, and we charge at the rate of one and one-sixteenth of a cent an hour for a ten-candle light. It makes no difference whether a consumer burns ten candles' worth an hour or one hundred, he is charged accordingly. Electricity is worth, as a commercial product, one-third more than gas, and therefore people will use it and pay one-third more for it than they will for gas. Of course, the system is not yet by any means perfect, but I am constantly working at it, and in three months' time I will have it down pretty fine, as the saying is. I do not consider the lighting of the streets as of any importance whatever, and have never had my attention directed to it. My system is perfect, and now I am prepared to go ahead. In the first place people said that the wires could not be laid underground. I have fully demonstrated that they can. The lighting of the streets does not represent one-fifth of the future possibilities of the business that I have been stirring for, but it is the miles and miles of houses with the 46, 86, and 88 per month from the thousands of customers that I am after. The result of the experiment in this district now being developed will tell this story. If it is such as to satisfy the capitalists that it is a success, which I have no doubt it will be, other districts will be solicited as fast as the plants can be laid and the stations established. I fully expect in time to light the whole city of New York by means of electricity."

It will be remembered that our issue of October 16th contained some statements made by Mr. Edison to the reporters of two of the daily journals of New York city. It will also be recollected that Mr. Edison, and his system seemed, stated quite positively that nothing was going wrong in the working of his scheme for incandescent lighting—in fact, that "everything was lovely." That this was not "all rose" would seem to be proven by the following interview which he had with a reporter of the New York *Daily World*, on Nov. 3d, and which is here reproduced.

SNOW ON HIS LOOM.

The Edison Electric Light Company, which has secured the right to light all the buildings of the city with electricity, subject to the option of the owners or occupants of the buildings, has been for months laying wires throughout the district bounded by Spruce, Nassau and Wall streets and the East River. The city has been divided into thirty districts, and the one just mentioned is the first to be developed and is intended to demonstrate the practical workings of Mr. Edison's district system. The station is in Pearl street near Fulton, and there are already six immense dynamo machines, each one by a 200-horse power engine, completed and ready for operation. Each dynamo is capable of furnishing sufficient electricity to run 1,400 lights, and so, when the whole district is completed, there will be over 14,000 lights to furnish, it will be necessary to have six more similar machines to operate the entire district. The six dynamos already completed and set up were ready for use four or five weeks ago, but when they came to be tested efforts were found to exist in the machinery which were at once recognized as serious and which it has taken Mr. Edison all that time to overcome. Each engine and dynamo are on one bedplate, and form one machine. The idea was to turn all the electricity generated by the six machines into one set of mains. When the experiment was tried, however, the result was not what had been expected. The diffi-ty, as explained to a *World* reporter by Mr. Edison, may be summed up as follows:

"I found on trying the experiment," said Mr. Edison, "that the trouble was that when the electric current from two dynamos was united it was impossible to make them work smoothly, for the reason that if one engine ran faster than the other the fast engine would take all the load off the slow one, and the slow engine would be run merely as an electro-motor. The result of the first experiment was such as to astonish the engineers and every one who witnessed it, and came near proving serious. When the current from the second dynamo was turned on, first one engine and then the other would go like lightning, and first one and then the other was converted into a motor. One of the engineers, witnessing the effect, shut off steam, and still his engine was running just as rapidly as before. He came running towards me as white as a sheet, exclaiming: 'My God, Mr. Edison, what is the matter? I have shut off the steam, and yet my engine is running at lightning speed, and I can't stop it!' In addition to the 200-horse power engines running at a

It therefore seems to be in the interests of the public that strong district companies should be established, to which the local authorities may look for the supply of light, and to which, rather than to the Board of Trade, or, in the latter, a multiplicity of undertakers should be encouraged. Nothing, however, can be further from the wish of the Board of Trade than to create a monopoly, so that should the original undertakers exercise their powers inefficiently, or overcharge, or otherwise dissatisfy the public, the vestries or other authorities would be readily resorted to. It would appear that the metropolis, if the Board of Trade can only be induced to take a liberal and statesmanlike view of the situation, is within reach of the adoption of a scheme for the lighting of London which, while not fettering the Board of Trade unduly, would offer inducements to capitalists to embark in electric lighting undertakings with confidence in the ultimate success of the undertaking, and duly to safeguard the interests of the public.

We are, sir, your obedient servants,

WALTER WEBB & CO.

28, Queen Victoria-street, E.C., Jan. 31.

May 12, 1883.

THE STATIST.

HOUSTON ELECTRIC LIGHT AND POWER SUPPLY COMPANY.—According to the report, the available balance is $19,385. This allows the following appropriations:—A dividend of 5 per cent. upon the ordinary shares, £5,000 to the redemption off the pavilett and concession account, £3,000 to reserve fund, and £1,000 carried forward. The amount of distribution would have been larger, but the directors had not considered it right to do so, as the concessions for Yorkshires, Staffordshire, Warwickshire, and the concessions for Yorkshires, Staffordshire, Warwickshire, and the concessions for Lancashire, would require a large expenditure in connection with the meeting held on Wednesday, the chairman said that they were prepared a dividend of per cent. on £2,000 for the year ended and conversions account, in place £3,000 to the reserve fund, and to carry forward £1,085. With regard to the Lease for control, they were advised that they had a strong defence in the event of litigation with the licensees; but it was suggested to them that it would not be wise in the interests of the shareholders to enter into protracted litigation, and it was pretty generally considered that the ultimate result of which might be highly prejudicial to the proper business of the company. After long consideration, they therefore resolved to take the advice of their counsel—to repay the money they had received, and to hand back the lease to the receiver; except those for which they had sustained from the reticence of that company on this important point. A suit was pending between the company and the Brush Company. They had great difficulties to contend with, owing to the tremendous monopoly of the gas companies. The Electric Lighting Act, which at first seemed to be adverse to their interests, was really a great help to them, for it had given Parliamentary recognition to a great fact, and though only tentative it had legalized a position which was to enjoy immunity. It had been said that no public electric lighting contract had yet shown a profit. He was not prepared to admit the accuracy of the statement, but he should like to know what gas company could show a profit from the first week lighting if it had not the privilege of the private lighting? With their new Parnell meeting they could, he anticipated, serve a district that no gas company had shown a profit. Mr. Robert Hammond, in the course of a lengthy speech, stated that the Board of Trade had been in communication with their electric light which had shaken confidence; and in the past few days he had received from himself direct confirmation of the inquiries. They were prepared to put up plant to supply 40,000 lights, and to erect a station to accommodate that number. They could not, however, be extended that it might be done at 1s. 7d. per light. He

DR. C. W. SIEMENS UPON THE DISTRIBUTION OF ELECTRICITY.

In another column will be found an address by Dr. C. W. Siemens, delivered before the Society of Arts, in London, of which body he is Chairman.

This paper may be considered as of more than usual importance for various reasons. It comes from a source of undisputed authority, for few men in our day occupy the commanding position held by Dr. Siemens as regards scientific acquirement, practical knowledge, and, more rare than either, a combination of both in a business way which has resulted in the accumulation of great wealth; in short, he is most eminently a man of science who has made science pay.

When the subject of removing his contract for the lighting of a portion of the city of London was under discussion last Spring, he frankly told the authorities that, while others perhaps might be able to afford to advertise their patents at the expense involved in furnishing electric lighting at prices paid previously to that time, he could not; and that the price would have to be increased. In other words, being largely engaged in commercial transactions, he could not see why he should light a part of London, except upon a commercial basis. In the case which he has assumed as a model in his address the Doctor professes to deal with the case in the same spirit; but among the other assumptions in which the Doctor excels most scientific men may be found his skillful use of the English language. It is not his mother tongue, but we must say that few who are born with an English tongue are so skillful in the use of it. The ease with which the plainest and simplest statement is made to cover not only a supposed scientific truth, but a plain practical fact which will result therefrom, has always some exemplifications in an address from Dr. Siemens—and an address of his is look for each in this address. After clearly stating the amount of light that should be required in a certain district equal to one-quarter of one square mile, and proceeding to deduct therefrom such portions as would not be included, or would have a tendency to increase his average too much, he makes an estimate for the expense of the establishment of necessary works, including machinery, engines, distribution, etc., for doing 25 per cent. of the lighting in a district one-quarter of one square mile in extent, at about $883,000—and this includes no house connections or interior fittings.

When speaking of working expenses, the Doctor, with all the ease and quietness of speech imaginable, assumes that his lights are run "six hours a day," and that "with coal at twenty shillings a ton, and a consumption of two pounds of coal per effective horse power per hour," the coal will amount to a certain figure, which is perfectly satisfactory to the Doctor; but any one adopting the standard of coal laid down must closely adhere to the conditions mentioned.

Does the immense establishment of the Siemens Brothers, at Greenwich, obtain all their power of every kind with an expenditure of two pounds of coal per horse power per hour? If so it is very economically managed as to motive power.

And the next matter is gas works. Here, with clearness and simplicity, the Doctor says: "The cost of establishing gas works would not exceed £80,000" ($400,000) as against £177,000 ($885,000) for electricity. Whether the gas works are to supply twenty-five per cent. of the light required, or the whole, is not mentioned. But the main interest is in the conclusion that the Doctor draws from his own comparisons, which are in substance—

That the future of the gas industry bids fair to be a bright one, in spite of electricity. Doctor Siemens, although so familiar as my one else with the capabilities and the possibilities of electricity, has always maintained the doctrine that gas had only good to look for from the introduction of electricity, and he is of the same opinion still; and when he says that incandescent electric lights are a luxury, to be enjoyed, perhaps, by the wealthy, but that gas is the poor man's friend, it certainly does not appear that electric light is to supercede all other forms of artificial lighting on the ground of *price*; not look much like a broad margin of profit for those who sell it "as cheap as gas."

[From the "Journal of the Society of Arts."]

The Cost of Electric Lighting.

At the First Ordinary Meeting of the Society of Arts, held on Wednesday, November 15th, 1882, Charles William Siemens, D.C.L., LL.D., F.R.S., Chairman of the Council, delivered the following address:

Having received the honor of being elected Chairman of the Society of Arts for the ensuing year, the duty devolves upon me of opening the coming session with some introductory remarks::

Only a few months have elapsed since I was called upon to deliver a presidential address to the British Association at Southampton, and it may be reasonably supposed that I then exhausted my stock of accumulated thought and observation regarding the present development of science, both abstract and applied; that, in fact, I came before you, to use a popular phrase, pretty well pumped dry. And yet, so large is the field of modern science and industry, that, notwithstanding the good opportunity given me at Southampton, I could then do only scanty justice to comparatively few of the branches of modern progress, and had to curtail, or entirely omit, reference to others, upon which I should otherwise have wished to dwell.

There is this essential difference between the British Association and the Society of Arts, that the former can only take an annual survey of the progress of science, and must then confide to individuals, or to committees, specific inquiries, to be reported upon to the different sections at subsequent meetings; whereas the Society of Arts, with its 3,400 permanent members, its 95 associated societies, spread throughout the length and breadth of the country, its permanent building, its well-conducted *Journal*, its almost daily meetings and lectures, extending over six months of the year, possesses exceptionally favorable opportunities of following up questions of industrial progress to the point of their practical accomplishment.

In glancing back upon its history during the 128 years of its existence, we discover that the Society of Arts was the first institution to introduce science into the industrial arts; it was through the Society of Arts that the late Albert, past-president, the late Prince Consort, that the first Universal Exhibition was proposed, and brought to a successful issue in 1851; and it was due to the same Society, supported on all important occasions by its present president, the Prince of Wales, that so many important changes in our educational and industrial institutions have been inaugurated, too numerous to be referred to specifically on the present occasion.

Amongst the practical questions that now chiefly occupy public attention are those of electric lighting, and of the transmission of force by electricity. These together form a subject which has occupied my attention for many years, my brothers for a great number of years, and upon which I may consequently be supposed to dwell on the present occasion, considering that at Southampton I could deal only with some purely scientific considerations involved in this important subject.

I need hardly remind you that electric lighting, viewed as a physical experiment, has been known to us since the early part of the present century, and that many attempts have from time to time been made to promote its application. Two principal obstacles have stood in the way of its practical introduction—viz., the great cost of producing an electric current so long as chemical means had to be resorted to, and the mechanical difficulty of constructing electric lamps capable of sustaining, with steadiness, prolonged effects.

The dynamo machine, which enables us to convert mechanical into electrical force, purely and simply, has very effectually disposed of the former difficulty, inasmuch as a properly conceived and well constructed machine of this character converts more than 90 per cent. of the mechanical force imparted to it into electricity, 90 per cent. again of which may be converted into mechanical force at a moderate distance. The margin of loss, therefore, does not exceed 19 per cent., including purely mechanical losses; and this is quite capable of being further reduced to some extent by improved modes of construction. But it results from these figures that no great step in advance can be looked for in this direction. The dynamo machine presents the great advantage of simplicity over steam or other power-transmitting engines; it has but one working part, namely, a shaft, which, revolving in a pair of bearings, carries a coil or coils of wire admitting of perfect balancing. Frictional resistance is thus reduced to an absolute minimum, and no allowance has to be made for loss by combustion, or badly fitting pistons, stuffing boxes, or valves, or for the jerking action due to oscillating weights. The materials composing the machine, namely, soft iron and copper wire, undergo no deterioration or change by continuous working, and the depreciation of value is therefore a minimum, except where currents of exceedingly high potential are used, which appear to render the copper wire brittle.

The essential points to be attended to in the completion of the dynamo machine are the generation of induced currents in the iron, and the placing of the wire in such a position as to make the whole of it effective for the production of outward current. These principles, which have been clearly established by the labors of comparatively few workers in applied science, admit of being carried out in an almost infinite variety of construction forms, for each of which may be claimed some real or imaginary merits regarding questions of convenience or cost of production.

For many years after the principles involved in the construction of dynamo machines had been made known, little general interest was manifested in their favor, and few were the forms of construction offered for public use. The essential feature involved in the dynamo machine, the Siemens armature (1856), the Pacinotti ring (1861), and the self-exciting principle (1867), were published by their authors for the pure scientific interest attached to them, without being made subject matter of letters patent, which circumstance appears to have had the contrary effect of what might have been expected, in that it has retarded the introduction of this class of electric machine, because no person or firm had a sufficient commercial interest to undertake the large expenditure which must necessarily be incurred in reducing a first conception into a practical shape. Great credit is due to Messrs. Gramme for undertaking the initiative in the practical introduction of dynamo machines embodying those principles; but when, five years ago, I ventured to predict for the dynamo-electric current a great practical future, on a scene of time mitting power to a distance, those views were still looked upon as more or less chimerical. A few striking examples of what could be practically effected by the dynamo-electric current, such as the illumination of the Place de l'Opera, Paris, the occasional exhibition of powerful arc lights, and their adoption for military and lighthouse purposes, but especially the general accomplishment of the much desired lamp by incandescence in vacuum, gave rise to a somewhat sudden reversion of public feeling; and you may remember that in the month of last February, affecting the value of gas shares, which ensued in 1878, when the accomplishment of the subdivision of the electric light by incandescence was first announced, somewhat prematurely, through the Atlantic cable.

From this time forward electric lighting has been attracting more and more public attention, until the brilliant displays at the exhibition of Paris, and at Crystal Palace last year, served to excite public interest to an extraordinary degree. Now companies for the purpose of introducing electric light and power have been announced almost daily, whose claims to public attention and support in many instances were based in some cases only very slight modifications of well-known forms of dynamo machines, of arc regulators, or of incandescent carbon lights, the merits of which rested rather upon misconceptions than upon any scientific or practical proof. These misconceptions were supposed to be of such superlative merit that gas and other illuminants must soon be matters simply of history, and hence unwarranted speculative excitement. It must be borne in mind, however, that any great technical advance is necessarily the work of the scientific labor, and that when accomplished it is generally found that, so far from injuring industries, it calls additional ones into existence, to supply new demands, and thus gives rise to an increase in the sum total of our resources. It is therefore reasonable to expect that, side by side with the introduction of the new illuminant, gas lighting will go on improving and extending, although the advantages of electric light for many applications, such as the lighting of public halls and warehouses, of our dressing rooms and theatres, of our passenger steamers, our docks and harbors, are so evident that its advent may be looked upon as a matter of certainty.

Our legislature has been very slow in recognizing the importance of the new illuminant. In 1879 a select committee of the House of Commons instituted a careful inquiry into its nature and probable cost, with a view to legislation; the committee, at which they arrived were, I consider, the best that could have been laid down. They advised that applications should be encouraged tentatively by the granting of permissive bills, and this policy has given rise to the Electric Lighting Bill, 1882, promoted by Mr. Chamberlain, the President of the Board of Trade, regarding which much controversy has arisen. It could, indeed, hardly be expected that any act of legislation upon this subject could give universal satisfaction, because, while there are many believers in gas who would gladly oppose any measure likely to favor the progress of the rival illuminant, and others who wish to see it monopolized, either by local authorities or by large financial corporations, there are others again who would throw the doors open so wide as to enable almost all comers to interfere with the public thoroughfares, for the establishment of conducting wires without let or hindrance.

The law as now established takes, as I consider, a medium course between these diverging opinions, and, if properly interpreted, will protect, I believe, all legitimate interests, without impeding the healthy growth of establishments for the distribution of electric energy for lighting and for the transmission of power. Any firm or lighting company may, by application to the local authorities, obtain leave to place electric conductors below public streets and roadways in such positions as may be mutually agreed upon, thoroughfares, subject to such conditions as may be mutually agreed upon; the term of such license being limited to seven years; or an application may be made to the Board of Trade for a provisional order to the same effect, which, when sanctioned by Parliament, secures a right of occupation for 21 years. The license offers the advantage of cheapness, and may be regarded

American Gas Light Journal.

ANOTHER VICTORY AGAINST ELECTRIC COMPANY.—In the case of the Gramme Electric Company against the ARMOUR & HOCKHAUSEN Electrical Company, in a suit which was brought by the former to restrain the latter from employing the Gramme-pirano electric machine, decision adverse to the complainant was lately rendered by Judge Blatchford. The defendants contended that as the Gramme patents in Austria had expired in 1880, the American patents also lapsed at the same date, and in this view Judge Blatchford coincided.

LIGHTNING EXPERS AN ENGLISH COAL MINE.—The Newcastle *Chronicle* states that a most unusual and extraordinary occurrence took place at Dinnington colliery, Newcastle, England, during a severe thunderstorm.

The electric fluid seemed to strike the wet winding rope of the west shaft in the direction pointed upon the pulley. One current passed down into the winding engine-house, where it was seen to flash up and down the foot pump below the level of the floor, and quite illuminated the place at the time; another current passed down the rope to the bottom of the shaft, a depth of 35 fms., striking the cage, which fortunately was standing upon the bottom at the time, and exploded. The cassetter describes it as like a bell of fire falling upon the iron flat sheets at the bottom. He had his hand upon the cage, and received a smart electric shock, and was nearly blinded by the flash for the moment, but fortunately received no personal injury. The shaft is fitted up with round wire rope guides for two cages; those guides are suspended from the top of the pulley frames or head gearing, and secured at the bottom with heavily-weighted levers. Those iron rope guides would probably act as lightning conductors, and thus lessen the shock of any excess of electric fluid by carrying it off into the pump. Had the cages been running in the shaft at the time, and the shaft fitted up with the usual wooden guides, serious damage might have been caused, which would have been most difficult to account for or explain. After careful examination of the frames, pulleys, ropes, shaft, etc., no injury could be detected.

American Gas Light Journal.

Street Lighting in Fond du Lac, Wisconsin.

A number of the residents of Fond du Lac, Wis., have concluded that the electric light is neither what has been claimed nor expected of it, and consequently are much displeased with the workings and effect. The disappointment is the more severe considering many of these were advocates of the town's system of lighting. On Division, Barney, Linden, Second and other thoroughfares residents are now negotiating for a continuance of gas lamps at or near their residences so that the pedestrian may have light. Division street, east of Portland, will soon be lighted by gas, paid for by private individuals, while on the corner of Second and Barney streets the light of a particular favored that a number of industrial and wealthy citizens, and all heavy taxpayers, will petition the council to repudiate the electric light as per contract, after the expiration of 60 days, as not satisfactory, nor up to thousand and promised.

SEPTEMBER 23, 1882.
THE TIMES.
THE ELECTRIC LIGHTING ACT.

TO THE EDITOR OF THE TIMES.

SIR,—Are our local authorities alive to the fact that during the next four months a monopoly may be established for lighting their district by electricity?

By section 3 of the Act of Session and year of reign, before the 1Pth inst., 'apply to the Board of Trade, who may grant a license to supply electricity for public and private purposes. This is with the consent of the local authorities; but this clause is spoilt by limiting the time to seven years, which, unless altered in the Provisional Order, will probably make this clause, which is a good and practical one, unworkable.

By section 4 the Board of Trade, without the consent of the local authorities, can grant a provisional order "as such period, whether limited or unlimited," after the local authorities have had notice, subject to this order being submitted to Parliament, and subject to any opposition against the scheme before a Parliamentary Committee. A pleasant prospect for the lawyers!

"May the local authorities should have notice is made apparent by the rule issued by the Board of Trade in August—viz., if the local authorities choose to apply for a license or a provisional order, they will have plenty over other persons applying.

"Provided, that there shall be the grass grow under their feet." In the past, many a fortune comes from a large number of companies have been started so as to be ready notifying their intention to apply for a license of Trade under both sections, and possibly the one license has been adopted in every other district. Each company desire to obtain the start.

2. That the local authorities are well taken care of under clause 3. Whether the Board of Trade can be made to do so is doubtful. They will probably grant provisional orders with discretion. They may establish a monopoly for the district system all over the country, or they may allow half-dozen systems be tried in one street. They may leave it to the solvency of the companies, or they may let it to others without. I think it possible that the local authority may apply for a license, to protect themselves; but then will the Board force the ratepayers to light all their streets? Will they give the ratepayers time to see what the best streets, and will they hold us to do the work all at once, or in blocks of a mile, as I see recently proposed in New York by Sir Julian?

Parliament has given no compulsory power to purchase lands. This will, I think, render the Act unworkable.

Your obedient servant,

46, Cannon-street, E.C., London, Sept. 21. CHARLES HOSKOLD.

in the case of iron in pure air, but not where it comes into repeated contact with water or carbonic acid. An interesting phenomenon has likewise been observed on railways. It has been found that iron sleepers and spikes rust very much if the line is not used for some time. It is assumed that iron bodies are more liable to rust in a state of rest than if they are exposed to vibration from time to time, in which case, perhaps, an electrical effect comes into play which lessens the affinity of iron to oxygen.

In demolishing old buildings, there are often found iron cramps, blocks, etc., which, so far as they are surrounded by mortar, are completely free from rust, just as if they had come from the forge. A similar phenomenon has been met with by M. Vicat, a French engineer, when he had the anchor fastenings of several suspension bridges exposed which had been put down thirty years before. Where the iron in the masonry was surrounded by rich mortar, there was not a sign of the formation of rust, whilst the continuations of the anchors in hollow spaces were rusted to such a degree as to have lost two-thirds of their former dimensions. It has been frequently observed that iron does not oxidize in water if small quantities of caustic alkalies, or alkaline earths, are solved in it, by which case acids of whatever nature would be excluded. It appears that the above experiences have served as the basis for the rust protective paints invented by Herr A. Riegelmann, of Hamm (Hanover). He adds to his paints caustic alkaline earths, (baryta, strontia, etc.) By coating iron with them, it is said to be in the same state as the anchors of suspension bridges in lime mortar. Although simple coatings of such paints, owing to their slight thickness, cannot contain much alkaline matter, as is the case in walling in iron, alkaline effects will show themselves as long as they contain a certain percentage of it. But in any case these paints are free from noxious acids, which cannot be said of all other paints for iron. Should the paint be found in practice to possess the protective properties claimed for it, a step in advance would have been taken in the preservation of iron, and its greater application would be ensured.

The Buffalo (N. Y.) Electric Street Lighting Scheme Vetoed by Mayor Manning.

Mayor Manning, of Buffalo, N. Y., presented to the Buffalo Common Council, at its meeting in August, a veto of the action of the Aldermen authorizing the Comptroller to contract with the Brush Electric Light Company to light certain streets of the city with electricity. It is particularly gratifying in these days of corrupt, degenerate and extravagant systems of municipal government, to consider that some exceptions to the rule may be still found; and more than pleasing, it is comforting to find one exception to the rescues, clear and cogent, given by Mayor Manning in sustaining the position taken by him in this matter.

The electric lighting companies interested at one time to have taken a firm hold upon the affections of the solons at the head of municipal affairs in certain cities in the interior of the State; and some of these places find themselves burdened with contracts for lighting streets which they would very much like to cancel. Buffalo's Mayor has given the subject cool and calm consideration, having arrived at his determination on grounds which admit of no other interpretation than that they were solely for the best interests of the municipality of which he is the official head. The document is as follows:

"I return without my approval the following resolution adopted by your Honorable Body, on the 23d of July, viz.:

"That the Comptroller be and is hereby authorized and directed to contract with the Brush Electric Light Company for lighting certain streets streets with electric light from August 1, 1883, to August 1, 1884, at their bid of 55 cents per lamp per night; lights to be placed subject to the order of the Commissioner; also that the gas light companies shall discontinue all lamps in street crossings of a distance of 200 feet where electric lights are placed on the corners; the city reserving the right to discontinue any or all lights at any time during the term of contract, and in case of failure of any electric light to burn the full time, pro rata reduction shall be made for the time light fails to burn.

"On the 11th of May last you adopted a resolution authorizing the Comptroller to contract with the electric light company to light certain streets therein named. This resolution was returned without my approval, and I think no subsequent action was taken upon it. In the authority contained in the foregoing resolution of July 23, the same streets are included, and in addition thereto the Comptroller is authorized to contract with said company for the lighting in whole or in parts of thirteen other streets.

"In my communication of May 28 last, I stated somewhat at large some reasons why I could not yield my assent to the said resolution of May 14. The reasons apply with equal force to the resolution above set forth. I will not trouble you with a re-statement of them now, but respectfully beg leave to refer you to them as useful review and re-consideration. In regard to the last resolution I beg leave to make some additional suggestions. The street named in it is to be lighted instead of being 41 miles in length as stated in my said communication are according to a computation of the engineer 65,700 feet, or over 12 miles exclusive of parts of streets now lighted by electric light and the sum proposed for each electric light per night instead of 65 cents as at first proposed is now to be 55 cents. But I am satisfied that does not substantially change the position heretofore taken by me as to the comparative cost of gas and electric lights. In my said communication I stated that the difference in favor of gas was more than 55 per cent.; and on further examination and from such information I have been able to obtain, I am confirmed in that conclusion.

"As I learn from the parties concerned, it is not disputed that the interval between electric lamps should be not less than 600 feet, and that the usual and proper interval between gas street lamps should be 125 feet. There may be some exceptions to this rule, but the average distances are, as I am assured, as here stated. Different theories of computation have been adopted, but here is a basis of simple, ascertainable facts, viz: The number of electric lights to be furnished in a given district and the number of gas lamps in the same district. These being ascertained, there is no longer any question as to the comparative cost. It thus appears:

"Whole distance of streets to be lighted 65,700 feet. Divide this by 600 feet, the intervals between the electric lights and gives the number of lights at 104.

"Cost of each electric light per year, $200.75.

"One hundred and sixty-four electric lights at $200.75 gives the total cost per year $32,923."

COST OF GAS.

"Divide the whole distance as above stated by 125 feet, the interval between the gas lamps and it gives the whole number of lamps 525.

"The total cost of maintaining the 525 gas lamps at $56.45 each per year as proposed by the the gas companies, $13,012."

Comparative Cost Per Year.

Electric light	$32,923
Gas lamps	13,012
Difference per year	$19,911

"I have given this matter the most careful consideration, and I am confident that the above is as accurate a statement as it is practicable to obtain. It is based, as will be seen, upon the number of electric lights and gas lamps actually to be used and cannot be changed by suggestions founded upon mere speculation and conjecture, and it is but the comparative expenses of these two modes of lighting to public streets. Should you have any doubts about this statement, it might be well for you to make such inquiry as to satisfy you of its correctness. In your resolution of May 14, which was disapproved by me, you provided for lighting a certain district at an expense of over $2,000 more than it could have been lighted for with gas, and now as your communication recites reasons given for disapproving the resolution you have adopted another resolution describing another district which you provide for lighting with electric lights *at a cost of nearly $20,000 more than it could be lighted for with gas!* and though the district is confined mainly to a particular part of the city, this large sum would under the provisions of the city charter, virtually have to be raised by general tax on the whole city; so that this is a question which affects all the property owners in the city, and it will be for you to determine how far your project of lighting these certain streets with electricity will meet the approval, not of any particular ward or locality, but of every ward and every part of the city. I am not advised, gentlemen, of the reasons controlling your action in adopting your resolution, nor can I even conjecture what they may have been. With a certain few exceptions all the lighted parts of the city are with gas, and this has generally been found quite sufficient for the needs of the public. You have not authorized the lighting with electricity (in addition to streets already so lighted) of more than twelve miles of streets, along more than six miles of which, as I am informed, no gas pipes have been laid. With most exceptions these are outlying streets mostly in very thinly populated districts, and some of them being hardly more than *country roads*. Yet you propose to light all these at a *rate of expense more than double that of lighting the most densely populated portions of the city!* If there is any reason for this it would doubtless satisfy the taxpayers of this city that they should be informed of it. Nor do I think that the people along some of these streets would be greatly pleased to have this project thrust upon them. As to such streets as Broadway and Genesee-street the inhabitants on them. As to such streets as Broadway and Genesee-street the inhabitants along them would not fail to petition for this *costly* light if they desired it. It would be the same with the people on the other streets. Yet so far as I can learn not a single such petition has been presented as to any of the streets, and I am not aware that any evidence has been furnished of the existence of such desire. This is significant of the little support which will be received from the great mass of taxpayers for this project authorized by your resolution as to placing gas in streets not now lighted, the situation is the same. As to placing gas in streets not now lighted, the situation is the same as at the time of my said communication of May 28. All the gas companies have given ample assurance in writing that they will extend their gas mains as your honorable body shall direct, specially including all the streets designated

London Times, Feb. 1883.

TO THE EDITOR OF THE TIMES.

SIR,—It cannot be denied that your able article of Monday last and the subsequent letters thereon have cleared the ground. On the one hand, local authorities will see the unreasonableness of expecting to have all their own way, and on the other, electric lighting companies cannot expect to succeed in their attempt to saddle the public with provisions so objectionable as those contained in their draft orders.

Although I fully reciprocate the wish expressed by Messrs. Walter Webb and Co., and am willing to discuss the question fairly and liberally and to surrender many considerations in the utmost extent consistent with our interest, it is gratifying to find that the views of the Chiefs of Trade are supported so fully by other local authorities. Such a scheme as that proposed by the Brush Company was never contemplated when Mr. Farrer gave his evidence before the Select Committee of the House of Commons, nor do I think one word in the evidence or in the Act itself which supports the mode of dealing with the area of supply.

In Chelsea the Brush Company propose to lay down 720 literal yards of lines for "incandescent" lighting and about two miles of lines for "arc" lighting. The former consists of a length of 250 yards from a central station in three different directions (that being the greatest distance for working incandescent lighting successfully), and the latter for street lighting, upon which system electricity may be transmitted many miles, from one central station. These lines are to cost £14,000, but the company does not propose to carry them out under two years, and as regards the latter, at the request of the local authorities only; I submit that it could not have been intended to give facilities for "experimenting" with an important district under so trivial a liability and for giving preemption for 30 or 40 miles of streets in consideration of the completion to supply less than half a mile for "private" purposes, the latter being the great purpose of the Act.

If Mr. Chamberlain is a practical man he will insist on a test case or cases being decided by the Board—say, Chelsea, where we have no competing company, and St. Pancras, where two commercial companies and may overlap one another. If the companies are satisfied with the Board's decision there may be an end of the matter. If the Board decides in favour of the companies' scheme as to area of supply we shall find the case before Parliament. The Board having given their decision, they could bring into the House of Lords a Bill to sanction the two schemes, on which both sides could be heard. We should have the best and practical talent in Local Boards and the case for dealing with lighting of this description, time and money would thus go before the Speaker's Counsel, the most highest authority in the land, and the Committee upon the two Bills having been selected and assisted would come to a satisfactory decision. Let the Board have no more than two months, by which time the terms of the other orders for the Metropolis, which have for the first time received the sanction of Parliament, will have become the law of the land, and the Board will be in the position of the whole country and of one entity for each of the two schemes to be carried out by the Metropolitan Board, the amount to be ascertained by Mr. Adam, the House of Lords' Taxing Master.

If my suggestion is adopted, thousands of pounds will be saved to the companies and the ratepayers, and the interests of the Board of Trade will not be compromised, and the effects of all the orders will be incorporated in the Bill. Parliament shall avoid the trouble both to consider at once, and broken down by cross-examination of public servants being put on the back of the Board of Trade Provisional Order Act, and of the other orders, and the Bill to sanction the details be passed by a Committee of their rather late counsel duties.

Your obedient servant,

CHARLES MORROP.

60, Carnon-street, S.G., Feb. 2.

THE TIMES, FRIDAY, OCTOBER 6, 1882

ELECTRIC LIGHTING.

TO THE EDITOR OF THE TIMES.

SIR,—In considering the question from the public view, there is complaint of the greatest importance which is—the system or plan to be adopted in laying down the mains in the streets. I have not a copy of the Electric Lighting Act before me, but believe I am right in saying that there is no special provision on this section of the subject.

If new companies are allowed to break up the streets, then there will be confusion and inconvenience, but, as pointed out in your leading article in The Times of the 30th ult., this will doubtless be guarded against by the Board of Trade.

But even if one company supply a given district it is hardly likely that mains of sufficient capacity to supply all the electricity that may be consumed in that district will be laid down at once. Any such inconvenient lamps may be required from time to time in increasing numbers, probably to be worked at various degrees of electrical pressure or electro-motive force; all the public have a concurrent pulling up of the streets as the system becomes more and more extended; now what I am leading up to is this, that it is of the greatest importance that proper subways should be constructed to start with, in which it will be easy from time to time to lay additional mains without constantly disturbing the streets and traffic; the wasting is cost in the long run will be great. The local authority ought, I think, to construct these subways, and make the charge for the purpose. There is no one point in the whole question more important than this.

As regards the cost of the electric light, and the cost of installation, it is quite waste of time for us here to talk about its probable amount and make estimates with such data as we possess, as we can only deceive ourselves, but are allowing American enterprise to lead the way; we may as well wait until the result of the lighting of the mile block, now being laid down for electric lighting by Mr. Edison, in New York, is ascertained from the actual thing. Referring to the estimated cost of the various dynamo electric machines, the data quoted in recent letters in The Times are more or less fallacious, because the cost cannot be ascertained with any degree of accuracy until large machines of various systems have been constructed.

In two years' time, if not renewed, the patent for the light of dynamo-electric machines, the Gramme—system, and then there will be a general fall in prices.

I am, Sir, your obedient servant,

7, Northumberland-street, W.C., Oct. 2. RADCLIFFE WARD.

TO THE EDITOR OF THE TIMES.

SIR,—Referring to the correspondence which has appeared in The Times on the subject of the Provisional Orders and the licences for lighting by means of electricity in different districts in Great Britain, I find that already steps are being taken by enterprising speculators to utilise the provisions of the Act for their own personal profit. Many of these Orders and licences have been applied for by persons wholly unconnected with existing electric lighting interests, and without the necessary capabilities to carry their schemes into a successful issue. Of course, the object these gentlemen have in view is, after they have obtained a Provisional Order, to sell it to some one of the existing companies, and thus make a profit by means of a species of black mail, which must, of course, ultimately come out of the pockets of the consumers.

I think you will agree with me that the Board of Trade ought to be most careful in not issuing any Licences or Provisional Orders unless they are satisfied that the persons applying for the same have sufficient capital to carry out the same, and that, if possible, some condition should be made that these Licences or Orders should not be transferable by sale.

I am, Sir, your obedient servant,

(OFFICIAL NOTICE.)

Central New York Gas Engineers Association.

OFFICE OF CENTRAL N.Y. GAS ENGINEERS' ASSOCIATION, Sept. 10th, 1882.

On account of the Meeting of the American Gas Light Association occurring upon the day set apart for the semi-annual meeting of the Central New York Gas Engineers Association, the members of the latter Association are earnestly requested to be present at the American Association meeting at Pittsburgh, where final arrangements for a session will be arranged.

CHAS. A. WHITE, *Secretary.* JOHN MCDONALD, *President.*

(OFFICIAL NOTICE.)

American Gas Light Association.

OFFICE OF AMERICAN GAS LIGHT ASSOCIATION, No. 42 PINE STREET, N. Y.

The Tenth Annual Meeting of this Association will be held in the city of Pittsburgh, Pa., on the 18th, 19th and 20th days of October. The first session commencing at 10 o'clock on the morning of the 18th.

Headquarters will be at the Monongahela House, where the sessions of the Association will be held. Special rates of board, three dollars per day, have been arranged for members and their ladies. Under charge of the Committee of Arrangements, Friday, October 20th, will be devoted to visiting objects of interest in the city, a trip to the mines of the Westmoreland Gas Coal Company, and to the usual hospitalities of the local gas companies.

Ladies who may accompany members will be cared for during the sessions of the Association by a committee, who will accompany them to various places of public interest in the city.

Members who intend to present papers are again respectfully urged to promptly notify the Secretary of the fact, as also of the subject selected, so that the Executive Committee may complete its programme, and all be enabled to secure proper presentation and discussion of their papers.

Any officer of a gas company, person skilled in gas manufacture or illuminants connected therewith, is qualified for membership in the Association, and can obtain blank forms of application by applying to this office.

WM. HAMMIT WHITE, *Secretary.*

THE STUDY OF ELECTRICITY.

A little more than four years ago those vicious heathens it is to supply it. luminating agents to the public were somewhat startled by the wonderful announcements sent forth by the promoters of schemes for electric lighting. Almost simultaneously, and from different systems based forth, and since then the records of the patent offices of the different nations of the globe bear wonderful testimony of the fertility of man's inventive genius in attempting to grapple with the practical working out of problems whose solutions were, to a very large extent, empirical.

The very science of electricity was in its infancy, and, as yet, the information empirically, and perhaps, in some instances, theoretically obtained, had not been brought together and formulated under fixed heads and subdivisions. Men of science, as well as practical men, have since devoted time and money to the questions involved; and in less than five years we have witnessed international exhibitions, and congresses of all nations, devoted to the formulating and crystallizing into language that shall be understood and uniform meaning, the principles thus far established of this almost new department of science. The results accomplished are alike creditable in the energy, patience and skill of the various investigators who, coming from both sides of the Atlantic, and from various nations, have met with so much success in attaining their ends.

The result of this is that enough is now known to place the subject of the application of electro-motive force either for the production of light, or for use as a motive power, beyond the pale of conjecture, assertion or preposterous. It is true, perhaps, that the relative economies of the different applications, as compared with those of other means, may not yet have been fully worked out in detail; but we are happy to state that, so far as lighting is

THE TIMES.

DR. C. W. SIEMENS ON ELECTRIC LIGHTING.

TO THE EDITOR OF THE TIMES.

SIR,—Referring to your report of Dr. Siemens's address and to comments thereon in your leading article of Nov. 16, I trust you will permit me to direct attention to some points that may tend to modify the effect of the statements therein contained.

First, as to the comparison instituted between gas and electricity, it should, I think, be borne in mind that Dr. Siemens is an inventor and advocate of various systems for the more effectual utilization of gas and that he, therefore, occupies the position rather of an advocate than of a judge. For he is from me to impute any unworthy motives as influencing the judgment of so highly distinguished a philosopher; but, seeing that this philosopher is no less distinguished as a man, shrewd man of business, I think I may, without giving offence, recommend the exercise of caution in implicitly accepting the opinions of such men.

Secondly, I may point out that by Dr. Siemens's own showing eight-hour power is equivalent to only about the smallest power of electric light, whereas the general calculation of cost proceeds upon the assumption that the seven hours' power is the full 16-candle power. It is true that for seven and a-half hours it is lighted and in the other to incandescent light, but it is yet to learn that quality has been attained and that the practical development of electric lighting results will be forthcoming to any considerable extent of what has already been proved to be possible.

Thirdly, it must be remembered that the firm of Siemens Brothers, and Co. (limited) has itself very recently conferred a practical monopoly of electric lighting upon the Swan and the formation of electric companies has discouraged a number of competitors into the field. Moreover, it is hardly to be expected to view cost comparisons with any degree of favour and if they volunteer advice to the public as to the economy of investing capital in their own undertaking, they are not likely to paint the picture in sweetest hues.

Fourthly, Dr. Siemens proceeds upon the assumption that electric lighting must necessarily involve the introduction of steam engines, and the question of a costly system of combustion between those stations and the points of consumption. He seems to assume the possibility of preventing electricity at the outset from consumption; yet if this indeed be practicable it must entirely destroy the value of the case. Actual experience is daily demonstrating its practicability, and the shareholders in electric companies may well regard the calculations of their directors with a considerable degree of complacency.

Fifthly, the story presented to the public is too worthy of invention to keep indefinitely. But not that we are prone to add invention, and to win untrammelled credence for the idle tales which Barnum, Hannum, Jacobs and many others could name, and which seems they have sought the aid of printed ink to carry out. But as to the most important particulars of the case, the public are hardly in condition to form any opinion upon the possession of any number of degrees of knowledge by any means the case that all of the certainly-favoured companies are burdened with large directors of this company, for many years advised him with the commercial results of their operations, ascertaining nothing but that the best electrical systems in vogue were those in force.

I am, Sir, your obedient servant,
HUGH H. HIRSCH, General Manager.
The "Imperial" Electric Light, Power, and Heating Company (limited), 9, Salisbury-street, Strand, W., Nov. 17.

American Gas Light Journal.

The Edison System.

The letter from a Washington correspondent which appeared in our columns of October 5th (p. 261) seems to have excited considerable interest as to the present status of the Edison system in New York city. It has also furnished the distinguished inventor an opportunity of explaining to the readers of the New York *Daily Tribune*, and other daily papers, what the proprietors of this paper are obliged to publish. If this statement is as accurate as some others which are credited to Mr. Edison, it can simply pass for what it is worth. Almost newspaper notoriety being a cause for fear, we can safely say that Mr. Edison never has shown the slightest alarm at its terrors. And silent the matter of gas stock holders being so much "down in the dumps," perhaps some bold holders of stock in the original Edison concern, who bought at $2,000 per share, will tell how it is that this same stock can now be purchased for $200 a share. If, at any time, Mr. Edison should see fit we will be much pleased to have him contribute to our columns a full, clear, and complete statement concerning what he has done in this field of artificial lighting, with the cost thereof, including a fair return upon the money invested; thus we shall be able to give to our readers an authoritative statement that should be satisfactory to Mr. Edison, at least.

The newspaper extracts which follow explain themselves.

[From the New York "Daily Tribune."]

"It was stated yesterday that Thomas A. Edison, the inventor, had met with a great disappointment in the failure of his electric light apparatus to supply as many lights as he had expected it to do. The statement originated in a letter written to the AMERICAN GAS LIGHT JOURNAL. A *Tribune* reporter called at the central office of the Edison Electric Light Company, and found Mr. Edison busy at his desk. 'Has the generator at the central station down-town failed to supply the number of lights which it was expected to?' asked the reporter.

"'Oh, you've seen that gaslight paragraph, too, have you?' replied Mr. Edison, laughing. 'Well, now, we began operations by furnishing 1,600 lights, and that is exactly the number we are furnishing now.'

"'Did you expect to furnish more than that?'

"'Not until we had completed certain additions to our engine; and when they are completed, we shall furnish more.'

"What about the street mains?

"'Why, we've never had any trouble at all. Any statement that we have had such trouble is absolutely false and without basis. Those stories have been printed in a journal that has to publish what will please the holders of gas stocks; but they will not be pleased at having any daily paper take pains of their statements, because that gives us publicity of a kind which they do not like. The fact is that our success is such as to alarm holders of gas stocks. We have had no trouble of any kind with our apparatus.'

"At the central power-station of the company, in Pearl street, it was said a greater number of lights would be furnished. The superintendent of the most successful parts of the company's work. The mains were put down in lengths of twenty feet, and each length was subjected at the factory to a test of resistance. The loss of current in conductors extending fourteen miles power. At this rate, if the whole of Manhattan Island were lighted through mains such as are now used, the loss by leakage would not amount to current the reporter was denied emphatically that they had met with any kind of shock or disappointment in their operations."

[From the New York "Sun."]

"Touching the Edison incandescent light, we have received the subjoined communication:

"'To the Editor of the Sun.—Sir: The statement copied from the AMERICAN GAS LIGHT JOURNAL, which appeared in your Saturday edition, in which the statement is made that my system of underground conductors was a failure, and that I had been greatly disappointed, is absolutely untrue, but the opposite being the truth, as any one may easily ascertain, the system being in daily use.

"'THOMAS A. EDISON.

"'October 7.'"

"In order that the value of this denial may be properly estimated, we reprint what we copied from the GAS LIGHT JOURNAL:—

"'His information was derived from an electrician just returned from New York, who, as I understand, was summoned to your city for consultation on the subject. My informant states that Mr. Edison has just met with the greatest disappointment of his life—the complete failure of his attempt to light 2,000 lamps with his incandescent lamps by his underground system of wires; but fifty houses could be lighted, the electricity being carried away owing to imperfect insulation. As the institution was supposed to be perfect the conclusion is that underground conductors cannot be made to work.'

"It seems to us that Mr. Edison should be more explicit, and not throw the burden on the public of ascertaining the facts. Does or does not his underground system suffice to light 2,000 houses? Does it at present light more than fifty houses? And was or was not an electrician summoned to New York for consultation on the subject? That the system is in daily use, and that Mr. Edison was not greatly disappointed are entirely consistent with the conclusion that his underground conductors cannot be made to do the work laid out for them."

American Gas Light Journal, June 2, 82.

Electric Light at Railway Stations.

The following is taken from the *Manchester Guardian*:—At Manchester for some months past the electric light has been in use at the Victoria and London Road Stations. At Victoria it was first introduced by the Lancashire and Yorkshire Railway Company, who have tried two systems of lighting by electricity. The London and Northwestern Company soon followed at Victoria, but did not introduce electricity in the lighting of their station in London Road. The Sheffield and Lincolnshire Company, however, took up the question and introduced electric lamps in their portion of the station. The Lancashire and Yorkshire Railway Company have given the light the longest trial, and their experience is that it has proved a complete failure. The light is brilliant, but it is marred by serious unsteadiness, and, besides, it has proved unreliable. On several occasions when crowded trains have arrived at the platforms the lights have suddenly failed, and the station has been plunged in darkness. Feeling that this was a great drawback to the efficiency of the electric light, the company have decided to discontinue its use, and on Saturday it was seen for the last time. On Sunday the station was lighted with gas in the ordinary manner, and for the present this will be continued. It is believed that the company intend to introduce improvements in the system of lighting, but that they intend to rely, at all events in the first instance, on their own engineers for suggestions. At the London and Northwestern end of the station on Saturday evening considerable inconvenience was caused by the failure of the electric light. A crowded train had just drawn up at the platform, but before the passengers were able to leave the carriages the light failed. The passengers were greatly alarmed and could not find their way about, and it was not until the gas lamps had been lighted that fear was allayed and quiet restored. Comment upon the above is unnecessary.—*Gas and Water Review.*

The Troy *Evening Standard* gives the following statement of the action of the Board of Aldermen of that city in relation to the proposition to light the streets by electricity—

At the meeting of the common council held Thursday, September 21st, Alderman Fox, of the Sixth ward, moved the adoption of a resolution offering James O'Neill, Edward F. Murray, P. P. Connolly, Thomas Galvin, Thomas Farrell, John H. Gleason, and Michael Cavanaugh, the exclusive right to introduce and operate the electric light in this city and light the streets with the same. If even ordinary decency had prevailed among the Democratic members, or if any regard was had for the public weal, the resolution would have been referred to a committee, but when Alderman Fox moved the matter be investigated by the streets and alleys committee, his motion was lost—12 nays, 7 ayes.

The affirmative votes were cast by the ring democrats and voted away the biggest privileges ever granted by the city. More than this, an absolute monopoly was created, and a few aldermen by their own votes constituted themselves a party with unlimited power for the ultimate end of defrauding the city. The seven men named by Fox's resolution are mere dummies in the matter, and merely represent seven aldermen who have gone into a blind pool speculation, and by obtaining the electric light franchise sell it to the highest bidder.

The conspiracy it is said was first hatched in the fertile brain of Alderman Hopkins. The thing was all settled some time before the city fathers met, but at the last moment one of the aldermen backed out. Aldermen Fox and Hopkins then introduced the subject of electric light to Alderman Martin Murphy. "If we put through this resolution," said Hopkins, "we will get something nice, and if you vote for it you can become one of the shareholders."

"This is rather short notice," said Murphy.

"Well," broke in Fox, "your name need not appear in the matter at all. I'll put Johnnie Gleason's name in the resolution and he will represent you."

"All right," replied Murphy, "I guess Gleason will do the right thing by me."

Great minds run in great channels and the great minds of the electric light cohorts of the common council run in a groove supposed to be lined with $50,000. It is not the purpose of the virtuous solons who contrived to pass the resolution for an electric franchise to establish for themselves a monopolitous franchise to the highest bidder. The Albany electric light company, which illuminates with the Brush system, and the United States company of New York are both anxious to buy the franchise for a good round sum, purchasing of course, that the aldermen guarantee a contract. The Albany company has purchased the exclusive right to operate the Brush system in Troy from the Brush company of New York city, and it is said has offered to pay $30,000 for the franchise recently granted to the seven virtuous citizens. The United States company will pay $50,000.

His honor, Mayor Grace of New York, recently wrote a letter to his honor, Mayor Murphy of Troy, asking him to use his best efforts to induce the city to use the United States light for illuminating the highways and byways. The reason for Mayor Grace's solicitude is that he is one of the largest stockholders in the United States company. By his efforts in New York he succeeded in having the city contract with his company for the illumination of certain streets from Canal street to Union square. Of course Mayor Grace's letter to Mayor Murphy and the presage of the present electric light resolution may be only coincidences, singular and striking, but the connection would seem to be as strong as that between sin and Satan.

In New York city the various companies own the lamps and lamp posts, and are paid seventy cents per night for each light. In Albany the city owns the lamps and lamp posts, having purchased them from the company for $125 each. The company is paid fifty cents for each light nightly. There are at present 325 lamps in the city, which are operated at a cost of $162 50 per night, or $59,312 50 per year. They has 696 gas lamps, which are illuminated for $14,400 per year. Leaving aside the cost of erecting electric light lamps and lamp posts, and computing only the actual running cost of the light in Troy, and estimating only for 250 lamps, the cost would be $125 a night, or $45,625 a year. More than triple the present outlay for illuminating the city.

"As soon as the electric light commissioners make their bargain with the United States or Albany company it is expected that they will rush through a resolution in the common council directing the contracting board to advertising the only person having a valid right to lay electric light wires will be there. They will then submit it to one of the companies and thus defraud the city and enrich themselves.

Taxpayers will eagerly look for the mayor's action on this barefaced attempt to rob the city treasury for the benefit of a few men who are noising more than cancers in the body of the people. The mayor need not veto the bill on any sentimental grounds, for if he consults his astute city attorney he will learn that it is against the statutes of the state to grant an exclusive privilege in any city to any company, not only because it is a monopoly, but because it acts as a bar to future progress.

Persons well informed assert the mayor is in a quandary. He has been given to understand plainly that if he defeats the pet scheme of the aldermanic coterie he need not expect their support for any of his favorites in the coming election. It is underrated his honor wants the matter to rest until the campaign is finished, but the aldermen have grossly eyes on the golden ring, and there is likely to be trouble in the democratic camp.

No matter what final action may be taken by the mayor, the taxpayers should at once stamp their disapproval of this attempt to wring from them by force money to fill the pockets of political vultures. If this scheme should prove successful its originator it would be but the forerunner for others more stupendous, and all citizens who are interested in the prosperity of the city, and in decent government, should not only oppose the scheme, but relegate to well-deserved retirement the representatives who made its success possible by their votes.

American Gas Light Journal.

Mr. Lane-Fox and His Predictions.

With reference to the lecture delivered by Mr. Lane-Fox, on "The Future of Electric Lighting," before the Royal United Service Institute, we find *Engineering* making use of the following—

"Now we, like Mr. Fox, believe that there is a great future before electricity, but we find a difficulty in keeping pace with him when he gives the rein to his imagination. In the first place, taking his own data, we work out the cost for him, with coal at 20s. per ton, to be rather more than a halfpenny instead of a farthing. But even with this higher figure the result is sufficiently good to please the most ardent depreciator of gas. An ordinary gas jet costs one-fifth of a penny per hour, so that if Mr. Fox's prophecy ever come true we shall obtain four times the light from electricity for the same price we now pay for gas. It is a pity that some clue is not given as to the possible direction in which the improvements by which this great reduction is to be made. To-day there would be a difficulty in getting a supply of incandescence lights at the price of gas, even if the consumer undertook the renewals of the lamps. Where then is this reduction of four times (Mr. Lane Fox himself gives it as 12 times) to come from? There is no likelihood of engines burning much less coal or of coal becoming cheaper. Dynamos already convert 85 to 90 per cent. of the energy delivered to them into current, so there is little hope in that direction. The only other factor is the lamp, but the lecturer appears to exclude that, for it is upon the energy retailed that he bases his calculation, and not upon the light. No doubt there is much room for improvement in incandescence lamps, and the discovery of a conductor that would endure a higher temperature could make a wonderful alteration in the cost of maintenance, but at present we see no prospect of such a discovery. We wish that Mr. Lane-Fox had been more explicit with his sanguine, and but furnished reasons that would have enabled us to share his rosy anticipations."

St. James's Daily Gazette, April 25th, 1883

The Edison Light in St. Louis.—Mr. Wm. T. Brownell, special agent for the organization of local branches of the National Electric Light Company, of New York, has been in the city during the past week and has perfected arrangements to illuminate the business part of the city. It is reported that a contract may have been entered into whereby the Edison Company will furnish the current for the entire system of electric lights, the latter are of considerable extent, and many Angelenos have no doubt visited the Edison Electric Light Company, at New York, to witness the operation of the system in operation. A contract for the entire system of electric lights in the business portion of this city is now under consideration, and it is expected that the matter will be definitely settled before the end of the present month. It is also reported that the Edison Company will erect a large electric light plant in this city, and that the system will be in operation by the 1st of January next.

NOVEMBER 18, 1882.
THE CHICAGO TRIBUNE:
WISCONSIN.

Social Scandal in the Lower Fox.

APPLETON, Wis., Nov. 17.—Edison's electric light is being introduced here all the way down the Lower Fox River Valley. Oshkosh and Fond du Lac introduced it during the summer, and now Appleton is following closely in that direction. Already a number of the large paper mills on the Lower Fox have the electric light in operation. A new building is now being erected solely for the purpose, it is said, of putting in another system of the large number that have recently been introduced in this section. The Edison system is preferred.

Gas versus Electric Lighting.

In view of the assertions going the rounds of the Press, as to the great "economy" of using incandescent electric lights for purposes of household illumination, the following letter, to the London *Metropolitan*, from H. Saxon Snell, F.R.I.B.A., will be of interest. Mr. Snell has studied the question very closely, and his statements are not those of bare assertion, but are the deductions drawn from actual comparisons of cost. The letter is as follows:

To the Editor of the *Metropolitan*:

Many hundreds of thousands of pounds have lately been invested in electric light companies upon the faith of statements made in prospectuses that the mode of lighting is as cheap, if not cheaper, than that by gas. As to public buildings, we are told that "the difference between the cost of gas and electricity, light for light, is largely in favor of electric light, as proved by the Brush arc system at South Kensington (a saving of £325 16s. 4d. having been effected during the nine months as compared with gas)." Then Sir William Thompson is stated to have "had his house fitted with incandescent lamps from cellar to attic to the entire banishment of gas, and the connection with gas pipes." Lastly, we have the statement of Mr. William Crookes, F.R.S., and director of the Gulcher Electric Light Company, that he has fitted up two rooms in his private house with electric lamps, and has effected a saving of £4 1s. 6d. per annum as compared with gas lights.

No wonder, then, that one of my clients, a public Board, deemed it its duty to ascertain the cost of lighting by electricity one of the large institutions under its control. It instructed me to obtain such estimates, and accordingly I applied to three of the most important electric light companies for specifications and tenders for lighting the building in question, merely stipulating that the work should be executed under the same general conditions as those employed in the contract for the supply of gas pipes and fittings.

In the result, three tenders were received for the execution of the works, amounting respectively to £5,500, £4,345, and £7,145. I then became my duty to make an estimate of what would be the annual cost of lighting the building, supposing one or the other of these tenders to be accepted, and I did so as follows from the gas furnished me by one of the companies in question, though I thought it my duty to inform my client that I considered many of these items to be considerably understated.

	No. 1. £. s. d.	No. 2. £. s. d.	No. 3. £. s. d.
Interest on first outlay at 5 per cent.,	275 0 0	217 5 0	157 3 0
Depreciation of plant and general repairs at 10 per cent.	550 0 0	434 10 0	314 6 0
Coals—*say* 5 tons per day, at 20s. per ton delivered	730 0 0	730 0 0	730 0 0
Oil, waste, etc.	52 0 0	52 0 0	52 0 0
Wages, 2 engineers at £3 per week	208 0 0	208 0 0	208 0 0
" 2 stokers at 30 shillings	156 0 0	156 0 0	156 0 0
Renewal of lamps after first year, and including additional breakage, bill assuming the average life of a lamp to be 1000 hours, and that the average rate of lighting would be 5½ hours daily	676 0 0	676 0 0	676 0 0
Total	2,446 0 0	2,272 15 0	2,029 9 0

As I was anxious that my report should be as far as possible be incontestable of question, I sent a copy of each of these estimates to the respective companies, with a request that they would point out any errors they might conceive to lurk in the foregoing estimates for the annual expense—viz., £2,204, £1,905, and £2,000, as against my own of £2,446, £2,273, and £2,029 respectively. These reductions were made in various ways, some conceiving 4 per cent. for interest on a sufficient allowance

NOVEMBER 22, 1882
THE DAILY NEWS.

Electric Lighting in the City.—Yesterday morning a deputation of the City Commissioners of Sewers held at Guildhall, Mr. Perkins presiding, the Streets Committee, Mr. Bell, Assistant Surveyor, brought a report in regard to the notices from various companies for the purpose of lighting the streets by the electric light. It appears that the Commissioners have given to light the City by electricity. The Committee therefore directed Mr. Bell, amongst other things, to obtain the opinion of some eminent electrician as to whether it would be practicable to light the City with the two conductors of various companies for lighting by different systems, and whether through the conductors so laid by the various companies, if desirable, by that means, could be also conducted the main electric light from the Guildhall Yard; and whether the conductors laid in a district by any company would be available for any other company, if desirable, by that means, to

Service Pipe Fused by an Edison Illuminating Wire.—Among other "dead sure" things claimed for the Edison System of incandescent electric lighting is the utter harmlessness of its current—it having been asserted over and over again that by no possibility could serious danger arise either to person or property from contact with the same. The "harmlessness" and the "weakness" of the Edison current is rather clearly shown by the following illustration which is an exact reproduction in wood of a photograph of a service pipe which formerly led into the buildings Nos. 121 and 123 Front street, New York city. Mr. J. W. Phyfe, who has his offices on

the first floor of the premises mentioned, uses the Edison light for purposes of illumination, the rest of the building being supplied with gas from the mains of the New York Gas Light Company. The gas service pipe was two inches in diameter, and entered the building alongside of the Edison supply wires. As nearly as can be ascertained (for the investigation subsequently made proved nothing conclusively) one of the electric light wires became reduced it to the condition as seen in the engraving. The escaping gas became ignited, causing an explosion, and setting fire to the premises; the flames were easily and speedily extinguished, so that no great amount of pecuniary damage ensued. This is mainly of interest from the fact that it entirely upsets the "perfect safety" theory so often advanced by Mr. Edison and his confreres.

Pond du Lac's Towers Heard from Once More.—On May 12, we announced that one of the electric light towers at Fond du Lac, Wis., was leveled to the ground during the prevalence of a storm of wind on the night of April 14. We also predicted, at the time, that some of the other structures of a similar nature would probably come down in the same manner. Well, this prediction is now verified. On the morning of July 16, the principal electric light tower, situated in the center of the town, suddenly tumbled. One portion of it, a piece weighing about 500 pounds, crashed through the roof of a saloon, demolishing a stove at which a woman was cooking; strange to say, she escaped injury. The loss is put at $2,000. It might be added here that no storm of any kind prevailed at the time. Wonder how long before New York will have a similar experience.

The authorities have at last reached the sapient conclusion, from the evidence presented, that it is no longer safe to trust the towers which still remain in position. The Mayor of Fond du Lac telegraphed the Electric Tower Company (the contractors who erected them) ordering the structures to be taken down. The tower company made no response, and so the city authorities, to guard against further accidents, are belaboring them (the towers) with guy rods. They never had to put "guys" around the lamp-posts. Moral, go back to gas; or better still, never "go back" on gas.

American Gas Light Journal.
An Electric "Leak."
Sept. 2, 1882.

On the morning of Thursday, August 24th, one of the Edison conducting mains, situated in Nassau street, near Ann, New York city, became injured in some manner, probably through the carelessness of the laborers employed by the steam heating company engaged in piping the downtown district. The consequence was that an escape of the electric current occurred, powerful enough to be felt by horses passing over the street in close proximity to the spot where the fracture existed. The strange antics of the animals when first experiencing the shock, created considerable amusement for the bystanders.

A reporter of the New York *World* had the following interview with Mr. Edison in relation to the "leak"—

"In the first place," said Mr. Edison, "the report that it would be impossible for the fluid to communicate with the horses unless their shoes came directly into contact with some metal is all a mistake. The thing can be, and, in this case, has been done. The disturbances was directly due to a very simple circumstance. A service pipe had been laid from the main to a printing office in an upper story of a house in Nassau street, passing through a liquor-beer saloon in the basement of the building. We had only got so far as the basement with our operations and the end of the pipe was left there, protected by a small metal cap. This cap, which had apparently not been properly screwed on, became loose and slipped on to the conductors, between which and the pipe enclosing them communication was thus established. The electricity, finding its way along the pipe, radiated in all directions in the earth, and a horse passing along the street near the base of the radiation, and forming part of what is technically called earth, would receive a shock sufficient to cause it considerable surprise, if not alarm. It was by some overweight, such as the most careful workmen are liable to, that electricity was in the service pipe at all, when we tested it yesterday we at once found a fault which it contained, for by our system we can locate faults with the greatest facility, and orders were given that it should not be connected with the machine. The branch, however, was supplied with electricity. But the force of the current that affected the animals was very trivial, equal to only some seven or eight cells of a common battery. Such a weak current could only affect the lower animals. All the steeplechasing that happened was simply due to the nervousness of the animals at the novelty of the sensation. At Menlo Park I have [illegible] tric railroad, and a horse crossing it will occasionally get a slight shock [illegible] become secured. Yet a man can take hold of the rails with impunity. [illegible] electro-motive force is equal to 100 cells of a Daniell's battery, which would cause a pressure of 100 volts—a very low pressure, indeed."

"Had you much difficulty in setting matters right?"

"We just took the service into out and disconnected it. You see it here."

Mr. Edison pointed to a short piece of iron pipe about three inches in diameter, containing two copper rods insulated from each other by means of an asphaltic compound. At one end was a flat iron box containing a quantity of the compound, and which Mr. Edison explained was used for making the connection between the service pipe and the main. The size of the conductors vary according to circumstances, the main conductors being equal to a copper rod half an inch in diameter, and the service conductors to rods of a smaller size."

"We were rather surprised at the very successful insulation we obtained by repeated experiment," said Mr. Edison. "We calculated that a certain length of pipe having a certain leakage, a hundred times the length would have a hundred times the leakage. We found, on the contrary, that by the use of one compound the insulation was in the ratio of no more than three to one. We tested three and one-half miles last night and the insulation amounted to 2,800,000 ohms, which is unprecedented for the size of our work and the necessarily rough and practical character of our machinery. Of course, compared with things like the Atlantic cable, the insulation is nothing extraordinary, but the instruments used for those purposes are of the most delicate and refined type."

"Do you expect soon to have your works in active operation?"

"Well, we are ready to go to work now, if the company pleased; but at present we are cutting in, and so on. I suppose in ten days we [illegible] 1,000 lights cut in. 'Cutting in' means establishing communication between the house and the main pipe. In the Nassau street district [illegible] 3,100 service pipes, and about fourteen miles of pipe altogether. [illegible] strict comprises 512 consumers. There are 14,011 lamps to be connected with these wires."

PROGRESS OF GAS AND ELECTRICITY.

As time goes on and the earlier excitements incident to the first introduction of so-called novelty and new discovery gradually subside, as the echo of the flourish of trumpets preceding the launching of the great schemes of stockers times dies away behind the rolling hours of three or four short years, a lull in the excitement, a quiet hour for actual investigation of facts is granted, and even the public, who are ever ready to grasp at novelty, and remove that impatient of the delay of careful investigation, becomes satisfied in time that there is a wide margin between the promises of enthusiastic "promoters," and the results obtainable under the ordinary working conditions of every-day practice.

...t four years ago we published a report, made by the Editor of this Journal, after a most careful investigation of the subject of electric lightings made under exceptionally favorable circumstances in Paris, where "the light of the future" was then brought forth under most favorable auspices. The opinions expressed in the report are true to-day than when they were written, if we may be pardoned the expression, for they are most fully borne out by the experience of the years that have elapsed since 1878. At that time the Avenue de l'Opera, the Place du Theatre Francais, and the Place de l'Opera, were refulgent with the beautifully clustered coming effect of the Jablochoff electric candle. Its use continued for some three years thereafter, but the traveler or the citizen looks in vain to-day for the electric light in any of those places, but instead, if one cares to notice, is to be found the improved street lighting by gas.

We are fully aware that the conditions under which the streets of Paris are lighted are exceptional; but this does not in any way affect the reasons for the discontinuance of the electric street lighting. That resulted simply from the inability of the company to continue the service, without financial loss, at the prices which were at first submitted as ample for proper compensation. In fact the manager of the company is said to have stated that they could not afford to continue the advertisement at so great an expense. A similar result was reached in London in at least one case—that part of the city in the vicinity of the Mansion House, which was most superbly lighted (regardless of cost) by the Siemens system. After one year's trial it was found that the price obtained, which was several times that previously paid for gaslighting, was not sufficient to warrant those supplying the electric light in continuing the service without a large increase in compensation.

ELECTRIC LIGHTING ON OCEAN STEAMSHIPS.

There is probably an application of the electric light more advantageous, or more conducive to the security of those interested, than its adaptation to the uses of those immense steamers that are engaged in plying between this country and Europe. When we consider the large and increasing number of our people who cross and re-cross the ocean every summer, the large number of ships employed, and the immense size of some of them, safety becomes a consideration of the first importance; and it cannot be denied that the incandescent light has been so adapted to the requirements of the case as to give great relief from the danger which must ever attend the use of open lamps at sea.

There is no steamship as yet which relies entirely upon the electric system of lighting; but there are several that have introduced it to a greater or less extent, with a degree of success, so far as the lighting is concerned, that renders it worthy of notice and commendation.

The steamer Servia, of the Cunard line, is said to be the largest commercial steamer afloat, excepting the Great Eastern, being 530 feet in length, 52 feet beam, 40 feet 9 inches deep, and having a measurement of 8,500 tons. She is propelled by engines of 10,000 horse power, while her screw is 23 feet 6 inches in diameter. Thirty-nine boilers and furnaces, all told, supply the power for all purposes, and steam power is employed for every possible purpose, in order to reduce to the minimum the manual labor required. A large

American Gas Light Journal.

REMARKABLE REPORT ON THE COST OF INCANDESCENT ELECTRIC LIGHTING.

Herewith is given the gist of a report to the American Electric Light Company, by Mr. E. P. Roberts, on the cost of incandescent electric lighting—

"I calculate that we can, merely allowing equal illumination, and not taking into account the immense advantages of incandescent lighting, compete with gas at 95 cents per M.

"The following is the data from which I have obtained the above result—

"Take a 600-H.P. engine—cylinder 26 x 45; pressure by gauge, 75 lbs.; revolutions, 100; pressure absolute, 90 lbs.; 28 per cent. cylinder condensation; assuming 7.65 lbs. of water evaporated per pound of coal; coal $4.25 per ton of 2,000 lbs.; clearance 2½ per cent.

	Cost of engine, $9,000.
Interest on cost of engine, per hour	.062

THE DAILY NEWS.

ELECTRIC LIGHTING IN THE CITY.

...on his report to the Electric Committee of the Commissioners of Sewers, Lieutenant-Colonel Haywood gives a favourable account of the experimental lighting of the Holborn viaduct by the electric light. The incandescent lamps are of course infinitely superior to the arc lamps, and the only reason for which one should be disposed to prefer the latter is the fact that the single gas lamp, which they displace, "is so dim, that it is not the object to which ordinary illumination is a great consideration, and this cannot be attained by the lamps system was about the ten-and-one-half feet apart. Lieutenant-Colonel Haywood says that the electric lamps in the Holborn which he visited (and there are other lamps are in course of erection to destroy the eye and the footway) there is no flickering, and no material variation in fluctuating power, as far as can be noticed by the ordinary observer, and the Viaduct is the most perfectly and well lighted. The Edison lamp, however, is by far the superior of the two, and the Holborn Viaduct supplies a mass of facts and figures bearing on the valuable experience already gained of lighting the City by the Brush, the Lontin, and the Swan systems. From the general statement it is contended that the cost of lighting by the Brush system was about two-and-a-half times as much as ordinary gas lighting, while the Lontin cost about three times as much. Under the three systems there is a loss of light (in proportion to quantity) of about one-fifth after the period of about 500 hours' use. Electric illumination should not be thought of, but on special occasions, and have practically no longer for themselves, the continued use of which would necessitate expenditure to an unjustifiable extent. The matter of this report has already been made public in the columns of the Times some considerable. It appears from figures attending in the report of the Electric Committee of the Commissioners of Sewers regarding the electric lighting, the cost of the light in the City, which will be considerably reduced by the proposed use of the Holborn Viaduct. Colonel Haywood in the purpose of lighting besides the commercial new districts in the east, north, and west of the City have divided into four districts, the boundaries of which appears from the tabular statistic that the competition between companies will be sufficient to secure the best service results, including the fixing of machinery, lamps, &c., varied considerably—the Brush Company's tender for one year being £1,600, or £1,800, or £2,000 against £611, the present cost of gas. In some instances, however, the Commissioners would with their leave to light private premises within the district. Colonel Haywood has also made inquiries as to the charge for lighting (exclusive of machinery, &c.), the same as for the gas saved, which the Commissioners recommend the Commissioners to proceed further in the matter. At present, the report of the Electric Lighting Committee, the Commissioners that, by the Bill now before Parliament, and the Corporation of London, by the Board of Trade, to be proposed to give power in the City to the Commissioners of Sewers, and to confer upon them the necessary powers to enable them completely the undertakings of that nature which they were given the powers of Parliament has decided that the Commissioners of Sewers should be the authority which should have the power to grant licenses for lighting streets, and that the Commissioners of Sewers should be the authority which would be responsible for the control of the electric lighting of the City by the Board, and the Commissioners are already empowered to which the undertaking operation. The Committee recommend that the Commissioners of Sewers now be informed the recommendations of the important questions involved in this document.

INCANDESCENT LIGHTS IN NEW YORK.

We are informed by the officers of the New York Gas Light Company, who partly supply the down-town district with gas where the Edison system has been introduced, that in the month of December last (1882) one hundred and two of the gas company's consumers were using the incandescence electric lights. During the month of December, 1881, the previous year, these same 110 consumers burned 1,025,000 cubic feet of gas, while during December, 1882, they consumed 618,000 cubic feet, thus making a difference of 427,000 cubic feet.

This difference may not all have come from the use of the electric light, as during the winter months the consumption of the down-town districts varies very largely with the state of the weather. A very dark, foggy or stormy day will sometimes increase the send-out 30 per cent. over what it would be on a clear, bright day.

One fact is evident, from the figures given, and this is that electricity does not do all the lighting for even those places where it has been introduced. A goodly quantity of gas seems to be needed; and, if rumors are true, a goodly quantity of money will be required to pay the electric lighting bills. Sample bills were sent round to the electric consumers, for the month of December, not for payment, but to show about what the cost of the new light would be; in most cases this cost amounted to about three times the price of all the gas used formerly, besides the cost of gas used at present.

Of course, the prices charged for electric light are subject to modification, from time to time, and they will have to be made satisfactory to consumers or they will not use the light.

There is some trouble about estimating by the candle power of the incandescence lights, as it sometimes happens that the bulbs become discolored on the inside, from some cause or other, and they do not then transmit the full volume of light which they are calculated to supply. This is not a new fear of renewals of lamps necessary to give the proper amount of light. The working thus far would rather tend to show that Dr. C. W. Siemens was right when he said that, "Electricity is a light of luxury, but gas is the poor man's friend."

American Gas Light Journal, Feb. 2/83.

Electric Light in China.

Nature says the introduction of western improvements into China by Europeans is evidently a work beset with many difficulties. Some years ago the only railway in the country was purchased by the government from the promoters and promptly torn up; but now the officials themselves are laying down railroads from the mines in North China to the nearest canal. The telegraph also had to encounter a vigorous opposition, from the authorities and people for many years; at present, however, the capital is connected by wire with the coast. The electric light is the latest improvement which has excited the suspicion and dislike of the Mandarins. The foreign settlement at Shanghai has for some time been lighted on the Brush system, apparently much to the comfort and jubilation of the denizens of the "model settlement," as the foreign part of the city is generally called. This grew, however, to have to be reckoned without the Chinese officials. They prob ably thought that where gas was introduced there could be no objection to electricity. The Chinese Governor of the district appears to be of a different opinion. He has addressed a letter to the senior Foreign Consul, translations from European papers, that horrible accidents have arisen from the use of such dreadful risks.

"Hundreds of thousands of lives might be destroyed, millions of lives might be lost; even the walls of the city might be blown down if anything went wrong with the machines. He has strictly forbidden his own countrymen to use it, and has peremptorily ordered those who have already adopted it to discontinue it forthwith.

NATURE

VIENNA INTERNATIONAL ELECTRICAL EXHIBITION

THE Vienna Electrical Exhibition was opened to-day to the public. The patrons of the Exhibition are the Crown Prince Rudolph, the Portuguese Crown Prince, the Princes of the Imperial family, the higher functionaries of the State, and the Corps Diplomatique were present at the opening ceremony. The attendance of the public was small; only 2000 persons have visited the Exhibition to-day, the weather being rainy. The Crown Prince, in a speech, which was afterwards delivered by Baron Erlanger, the president of the Exhibition Commission, said that it did not seem to be only by chance that the third and greatest Electrical Exhibition is held in Vienna—in the town in which, in 1833, lucifer matches were invented by Preschel, from which, in 1837, the tentative candle found its way through the whole world, and where the lighting of streets by gas had been suggested by the Moravian, Zinzar, before it was carried out in England.

The Exhibition, though still incomplete, promises a good display illustrative of the great progress made in practical electricity during recent years, and showing how the application of electricity for the various purposes of industry and of daily life is becoming more and more common. So far as we can see now, although the work of installation of the machinery and apparatus is not yet completed, the Exhibition will stand comparison with previous exhibitions as to the number and variety of exhibits and the arrangements of the whole. From the official catalogue published to-day we learn that there are 372 exhibitors, 23 of whom are from Austria, 133 from France, 68 from Germany, 22 from Russia, 16 from Italy, 10 from Denmark, 13 from America, and 27 from England. Thus the Exhibition is rather a Continental one, and it is generally much regretted that so few exhibits have been sent from England, which has played a leading part in the development of applied electricity.

A special feature of the Vienna Exhibition is the building itself—the Rotunda, built by Scott Russell, the eminent engineer, in 1873, covering with its annexes and courts a space of 15,000 square metres. The vast dome is 79 m. in height, and three galleries, the highest—the interior gallery—being 66 m. above the ground, make it well adapted for illumination by electric lamps. Everything has been done to make the Exhibition as interesting and attractive as possible. Between the Rotunda and the Praterstern an electric tramway will run. The Rotunda is brought into telephonic connection with the Opera. A gallery of the Exhibition building contains a model theatre lighted by incandescent lamps, where ballets will be performed and scientific lectures given by eminent specialists, while another gallery contains beautifully arranged and furnished interiors and the picture gallery. In the machine rooms the great boilers make a gigantic impression; they will supply the various motors with 1,500 horse-power to drive the electric machinery for lighting and transmission of motive power. In the nave are arranged the exhibits of different makes of compactes and also various scientific apparatus, of which further details will be given in subsequent communications.

Vienna, August 16

NATURE

THE VIENNA INTERNATIONAL ELECTRIC EXHIBITION

FOR two weeks, the arrangement of the machinery being nearly complete, the Exhibition has been open in the evening from 7 till 11. The effect of the illumination of the immense interior of the Rotunda and its annexes by the various incandescent lamps, and of the surrounding places which are lighted by Brge reflectors, is brilliant. The electric railway of Siemens and Halske between the Rotunda and the Praterstern is already in operation. The theatrical performances at the "Asphalteln" Theatre, which is lighted by 1500 Swan lamps fed by a large Ziemtrowsky alternating current machine, have also begun this week.

The series of lectures to be held at the theatre during the Exhibition was inaugurated on August 27 by Sir C. W. Siemens, with a lecture "On the Temperature, Light, and Total Radiating Power of the Sun." After a short introductory sketch of the nature of the terrestrial sources of light, the lecturer gave an account of the ratio of the three forms of radiant energy, viz. heat, light, and actinism, as produced by the sun and terrestrial light sources. Then referring to the difference between the statements of various astronomers and physicists relating to the temperature, he expressed his opinion that the temperature of the sun could not exceed 2000° C., and explained the experimental methods he used for measuring the solar temperature. The second lecture was delivered on Sep-

[1] A name or other surname of Jacob's one whose ends exactly coincide with the edges of the rectangle, and which is the greatest circle that can be bounded by lines within the margins of the rectangle in which it is inscribed.

tember 1, by Dr. Aron of Berlin, "On the Telephone and Microphone." In this lecture the principles were explained on which the construction of the different telephones and microphones is based. These were also mentioned the variations of timbre as produced by these instruments; according to the experiments of Helmholtz the higher tones are transmitted better by the telephone, and therefore the timbre becomes clearer, while by the simple microphone, as Dr. Aron has found, the deeper tones are better transmitted, causing a duller timbre, but this latter is avoidable by using microphones with metal rods. The lecturer explained also the principle of a new instrument, invented by himself, called the sensaphone. In this instrument the variations of the current in a coil of insulated wire are transmitted by means of a second coil joined to a telephone or microphone. Dr. Aron made experiments with his sensaphone at Berlin, and was able to hear signals, the distance between the two coils being 70 feet. A similar experiment was carried out by Dr. Aron in the course of his lecture, and we could hear the noise made by a Neef's interrupter for from the lecture room, using a Siemens' telephone; the distance between the two coils being 5 feet.

Electric lighting is very well represented at the Exhibition, and a variety of new incandescent and arc lamps is to be seen there. As to the number of lamps exhibited, the first place is taken by the Swan lamps. Nearly 2000 Swan lamps are distributed at the theatre, the splendidly fitted private interiors, and other parts of the building, fed by dynamo machines or by Pisare-Sellon-Volckmar accumulators. The durability of these lamps seems to be confirmed by a collection of lamps exhibited by Ganz and Co., used 1720 to 2330 hours. The carbon filaments do not show any damage, only the glass bulb being darkened by a carbon deposit. The exhibition of Edison lamps is not as extensive as it was at previous exhibitions. The Maxim lamps are used for lighting the Oriental pavilion and some of the interiors. The Lane-Fox lamps are also lighting some furnished apartments, and show the applicability of incandescent lamps for street-lighting under the "Ausstellungsstrasse." The lamp of C. H. R. Müller has a screw-like carbol carbon filament to make the emission of rays uniform in all directions. The U-shaped carbon lamp of the Greiner and Friedrich incandescent lamp is prepared from lamp-black and graphite, coal-tar being used as cement. The coal-tar, at first treated with sulphuric acid, is heated till it becomes an asphalte-like mass, to which lamp-black and graphite are then added, so that a spout paste is formed. By pressing this

American Gas Light Journal.

Lessening the Fire Risks of Electric Lighting.

The Society of Telegraph Engineers and of Electricians, London, England, through a committee composed of representatives of both bodies, have submitted the following revised rules to govern the installation of electric light wires. It is claimed by the inventor to have many advantages over the other incandescent lamps. It will be noted that the rules previously published by us in 1882 are materially changed.

I.—THE DYNAMO MACHINE.

1. The dynamo machine should be fixed in a dry place.

2. It should not be exposed to dust or flyings.

3. It should be kept perfectly clean and its bearings well oiled.

4. The insulation of its coils and conductors should be periodically perfect.

5. All conductors in the dynamo room should be properly supported, well insulated, conveniently arranged for inspection, and marked or numbered.

II.—THE WIRES.

6. Every switch or commutator used for turning the current on or off should be constructed so that when it is moved and left it cannot permit of a permanent arc or heating.

7. Every part of the circuit should be so determined that the gauge of wire to be used is properly proportioned to the currents it will have to carry, and all junctions with a smaller conductor should be fitted with a suitable safety fuse or protector, so that no portion of the conductor should ever be allowed to attain a temperature exceeding 250° F.

8. Under ordinary circumstances complete metallic circuits should be used; the employment of gas and water pipes as conductors for the purpose of completing the circuit should not in any case be allowed.

9. Bare wires passing over the tops of houses should never be less than 7 feet clear of any part of the roof, and all wires crossing thoroughfares should be sufficiently high enough to allow fire escapes to pass under them.

10. It is most necessary that joints should be effectually and mechanically perfect and united by solder.

11. The position of wires when underground should be clearly indicated, and they should be laid down so as to be easily inspected and repaired.

12. All wires used for indoor purposes should be efficiently insulated, either by being covered throughout with some insulating medium, or, if bare, by resting on insulated supports.

13. Where these wires pass through roofs, floors, walls, or partitions, or where they cross or are liable to touch metallic masses, like iron girders or pipes, they should be thoroughly protected by suitable additional coverings; and where they are liable to abrasion from any cause, or to the depredations

14. Where indoor wires are put out of sight, as beneath flooring, they should be thoroughly protected from mechanical injury, and their position should be indicated.

N.B.—The value of frequently testing the apparatus and circuits cannot be too strongly urged. The escape of electricity cannot be detected by the sense of smell, as can gas, but it can be detected by apparatus far more perfect and delicate. Leakage not only means waste, but in the presence of moisture it means destruction of the conductor and the insulating covering by electric action.

III.—LAMPS.

15. Arc lamps should always be guarded by proper lanterns to prevent danger from falling incandescent pieces of carbon, and from succeeding sparks. The globes should be protected with wire netting.

16. The lanterns, and all parts which are to be handled, should be insulated from the circuit.

IV.—DANGER TO PERSON.

17. Where bare wire out of doors rests on insulating supports, it should be coated with insulating material, such as india-rubber tape or tube, for at least two feet on each side of the support.

18. To secure persons from danger inside buildings, it is essential so to arrange and protect the conductors and fittings that no one can be exposed to the shocks of alternating currents of a mean electro-motive force exceeding 100 volts, or to continuous currents of 200 volts.

19. If the difference of potential within any house exceeds 200 volts, the house should be provided with a "switch," so arranged that the supply of electricity can be at once cut off.

American Gas Light Journal, May 7, 1882.

Award of Contracts for Public Lighting in N. Y. City.

The Gas Commission, which consists of Mayor Grace, Comptroller Campbell, and Commissioner Thompson, of the Department of Public Works, yesterday awarded the contracts for lighting the city for the year ending April 30, 1883. The contract made last year with the Brush Electric Light Company, for lighting Broadway from Fourteenth to Thirty-fourth street, Fourteenth street from Fourth to Fifth avenue, Thirty-fourth street from Broadway to Fifth avenue, and Union and Madison squares, was continued for the ensuing year. Last year the Brush Company were paid 331 cents per lamp per night, but this year a demand was made for 70 cents per lamp per night. While continuing the old contract, the Gas Commission refused to extend the Brush Company's territory, because of the greatly increased expense.

The United States Electric Light Company for the first time received the contract to light Battery Park, City Hall Park, Broadway from Canal to Fourteenth street, Washington Park, and Fifth avenue from Washington Park to Fourteenth street. The price agreed upon is 70 cents per lamp per night.

Contracts were awarded to the various gas companies as follows:

New York Gas Company, the district south of Grand street, at $17.50 a lamp per year; Manhattan Gas Company, the district bounded by Grand and Thirty-fourth street, at $17.50 per lamp per year; Mutual Gas Company, certain streets in the district between Thirty-fourth and Seventy-ninth streets, and the parks south of Thirty-fourth street, with the exception of Madison and Union squares, at $17.50 per lamp; Metropolitan Gas Company, the remaining streets in the district between Thirty-fourth and Seventy-fourth streets, at $17.50 per lamp; Harlem Gas Company, the district north of Seventy-ninth street, south of Spuyten Duyvil Creek and the Harlem River, at $19.50 per lamp; Central Gas Company, the Twenty-third Ward, at $20 per lamp; Northern Gas Company, that portion of the Twenty-fourth Ward known as West Farms, at $20 per year; Yonkers Gas Company, the remaining portion of the Twenty-fourth Ward, at $20 per

New York Herald, April 18.

American Gas Light Journal.

ELECTRIC LIGHTING IN DENVER, COL.—It is stated that, in proportion to population and territory, Denver can boast of a greater number of arc lights than any other city in the United States; and, by the way, Denver must in time be a well-lighted place, judging from the number of parties who are anxious to get established there in the business of supplying artificial light. What with the old gas company and the Brush electric company, the new gas company and the Colorado Edison Electric Light Company, we must conclude with the inhabitants of the place. The last-named corporation was organized about six weeks ago, and starts in with a capital of $100,000. The officers are as follows: Wm. Orton (son of Wm. Orton, late President of the Western Union Telegraph Company), President; Wm. Moore, Vice-President; W. D. Todd, Secretary; Wm. M. Orr, Treasurer; and S. T. Armstrong, General Superintendent.

STREET LIGHTING AT EVANSVILLE, IND.—Evansville, Ind., is at present lighted, as to its streets, by 818 street lamps, and these lamps are scattered over a large area, owing to the somewhat irregular manner in which Evansville has spread. The electric light folks are trying hard to get a foothold, and, as usual, make great promises. They claim that one of the arc lights will give as good if not a better service than six of the gas lights now in use, etc., etc. The Evansville *Daily News* does not seem to be very enthusiastic on the project, as witness the following:

"In order to illuminate the city by electricity, as originally proposed, it will require a fraction over 136 lights, at $312.50 each per year, or $42,500, to substitute that light for gas, which costs now $16,852.96 per year, or an increase of $26,140.04 yearly to light the same area. That it is the intention of the company to ask for another change in its contract with the city, so that it may be released from the lower clause, as we said before the election that lower system will not do.

"This sum is little in excess of the minimum figures given by the *News* before the election, which were $30,000. But the present calculation is but a conjecture, based on the way the lights are now placed at street intersections; and if we will assume that the company will propose to put up but two-thirds of the number named, or 90 lights, the cost will be $28,437.50, which seems to us as low as anything like the present area can be lighted with the electric light, or nearly double what it costs with gas. As it is evident that some such change is contemplated, we suggest to the tax league, if it is still in existence, that the payment of the money to the company, or any other money, unless it be a sum that is less than is now paid the gas company for lighting the same area, be enjoined as contrary to the law, which forbids the incurring of any more indebtedness, the city being already in debt beyond its constitutional limit.

"We freely admit that the reference to the tax league is sarcastic, now that so many of its members are stockholders or advocates of the substitution of the electric light for gas; but we trust that someone else, who is sincere in his objection to the increase of expenses, will take the hint and enjoin the payment of the first bill of the electric light company that shall be ordered paid by the council, unless it lights the same area now lighted by gas at a less expense."

BALTIMORE'S ELECTRIC LIGHTS.—There are 225 "arc" lights in the streets of Baltimore, Md. The price paid per lamp per night is 70 cents; the lamps burn all night. Since the reduction in price of gas to $1.00 per thousand, many storekeepers, who had hitherto been using the "arc" light, have discontinued its employment. With gas at this figure, it will even trouble kerosene oil to "keep the pace."

STREET LIGHTING AT HOUSTON, TEXAS.—The committee of the city council of Houston, Texas, to whom was referred the application of Dr. Pinckard, President of the Electric Light Company, to establish and maintain 50 electric lights in the streets of the above-mentioned city, reported in favor of allowing the electric light people to place in position 32 lamps instead of 50. The contract price is $25 cents per light per night. The committee say in their report, "It is true that the financial condition of the city at the present time is not very flattering, owing to some derangement in the collector's department, but it is believed that this matter will be adjusted within a few days when everything will resume its proper shape." Right on the back of this statement this same committee recommends that a contract be entered into whereby the city is pledged to pay a most exorbitant price for electric lighting. One or two more recommendations of a similar nature, it would strike us, would require that affairs in the bureau of audit might suffer "derangement," and necessitate a "readjustment" of the kind now so popular in the South owing to the efforts of Mahone and his able imitators.

Mr. T. P. White, Secretary and Treasurer of the Houston Gas Light Company, made a proposition on behalf of himself and associates; the proposition was referred to a committee consisting of Aldermen Kennedy, Thomas and Meyer, and is as follows:

To the Honorable Mayor and Aldermen of the City of Houston—Gentlemen: The Houston Gas Light Company hereby agrees to contract with the city of Houston to light with gas the street lamps on the line of its mains, and keep the same regularly lighted during the hours specified in the last contract made between the city and the gas light company, on the following terms and conditions:

80 lamps at $2.90 each per month	$232.00
100 lamps at $2.80 each per month	280.00
125 lamps at $2.70 each per month	337.50
150 lamps at $2.65 each per month	397.50
200 lamps at $2.60 each per month	520.00

The gas light company agreeing to keep said lamps in good order during the existence of the contract. Said contract to remain in force for a period of not less than one year and for not more than five years.

First action has not been taken in the matter, and we hope that when such action is taken there will not be need of any kind of readjustment whatever.

INCANDESCENCE LIGHTS AT NEW ORLEANS, LA.—The Edison system of incandescence lamps has lately been installed at the St. Charles Hotel, New Orleans, La. In mentioning the fact that such an installation had been accomplished, a writer speaking through the columns of *New Orleans Picayune* of date of April 2, mentions, among other things, that, "It is a remarkable and significant fact that Edison gets nearly three times as much light from a pound of coal as the gas companies, and herein lies the promise of its future usefulness." The italics are ours.

Mr. Carroll writes that he visited the hotel, and was much astonished at the difference between a real 16 candle light, and the incandescent light represented as equal to 16 candles. The light looked as red as an ordinary gas light; and, so far as Mr. C. could judge from the evidence of eye-sight, gave a light of 12 candles—*nothing more*. Some of the lights he did not think were equal to 12 candles. The average illuminating power of gas supplied by the New Orleans Gas Light Company during the year 1882 was equal to 16.6 candles. There are 250 lights in use in the St. Charles Hotel, and it is claimed that the total cost, including coal, wages, depreciation, interest, &c., is but $1.07 per hour. Very nice figuring certainly; but why is the Edison system not in more extended use throughout the country, if this is true?

NATURE

On Friday night a series of interesting experiments with the Jablochkoff electric light took place at the West India Docks, under the direction of M. Denayrouse. The apparatus used for the occasion consisted merely of an electro-magnetic machine worked by a small steam-engine, some insulated wires, and the electric candles, which are the invention of M. Jablochkoff, and composed, as we have already described, of two carbons placed side by side with a slip of insulating substance between them, which burns away with the carbon exactly in the same way as the wax of a wax candle is consumed with the wick. The first experiment in order to show the suitableness of the invention for dock purposes consisted in the lighting of four of the "candles" in a large yard. The light thus obtained, which was shaded by ground glass, brilliantly illuminated the inclosure, it being possible to read small print at a considerable distance from the lights, while at the same time the eyes were not affected by the glare, as is the case with the ordinary electric light. The second experiment was confined to the illumination of the top story of one of the large warehouses, and this, like its predecessor, was equally successful. A large vessel at the quay side was also lighted up, as also was a portion of the quay. The whole of the experiments were very successful, and it was stated that each "candle" gave a light equal to 100 gas lights. The light is said to be much less expensive than gas.

March 10, 1881

NATURE

An important experiment in electric lighting is about to be made in the City. If thanks the electric light has been used, as on the Thames Embankment and Waterloo Bridge, in conjunction with gas; but in the City the thoroughfares selected are to be lighted by electricity alone until it be continued all night. The first district begins with Blackfriars Bridge, and extends along Bridge Street, Ludgate Hill, the north side of St. Paul's Churchyard, and down Cheapside as far as King Street. The scheme is eight yards, and is to be lighted by the Brush system. At King Street the Siemens system will begin, and will extend along the rest of Cheapside, the Poultry, Mansion House Street, King William Street, and Gracechurch Place, and across London Bridge. The same system will be extended down King Street, Queen Street, and Moon House Street. The whole length of street covered by the Siemens light will be 1,321 yards. Another district to the south of these will be lighted by the Jablochkoff lamps, the Embankment. It will include Southwark Bridge, Queen Victoria Street, Queen Street Place, and part of Queen Street, a distance of 1,045 yards. The experiment is to be continued for a year, at an outlay of about £900.

NATURE

FIRE RISKS FROM ELECTRIC LIGHTING

A VERY strong and influential committee was recently formed by the Society of Electricians to draw up a series of rules and regulations not only for the guidance and instruction of those who have electric lighting apparatus installed on their premises, but for the reduction to a minimum of those risks of fire which are inherent to every system of artificial illumination. They point out that the chief dangers of every new application of electricity arise mainly from ignorance and inexperience on the part of those who superintend it up the requisite point. The difficulties that beset the electrical engineer are chiefly internal and invisible, and they can only be effectually guarded against by "testing" or probing with electric currents. They point out that defective insulation, undue waste of energy and the production of heat. These defects can only be detected by measuring, by means of special apparatus, the currents that are either ordinarily there or supposed constantly to exist. Hence, without frequent inspection, since the accidental failure on to, or the thoughtless placing of other conducting bodies upon such conductors might lead to "short circuiting" or the sudden generation of heat due to a powerful current of electricity in conductors too small to carry it.

The Committee point out this it cannot be too strongly urged that amongst the chief enemies to be guarded against are the presence of moisture and the use of "earth" as part of the circuit. Moisture leads to loss of current and to the destruction of the conductor by electrolytic corrosion, and the introduction of the conductor by electrolytic corrosion, and the introduction of "earth" as a part of the circuit leads to magnify every other source of difficulty and danger.

The chief element of safety is the employment of skilled and experienced electricians to supervise the work.

This would deal with the installation of the dynamo-machine, the fixture of the wires, the character of the lamps to be used, and the danger that accrues to the person.

To secure persons from danger inside buildings, it is essential so to arrange the conductors and lamps, that no one can be exposed to the shocks of alternating currents exceeding 60 volts; and that there should never be a difference of potential of more than 200 volts between any two points in the system.

If the difference of potential within any house exceeds 200 volts, whether the source of electricity be external or internal, the house should be provided outside with a "switch," so arranged that the supply of electricity can be at once cut off.

The rules are very valuable, and should be obtained by all who are contemplating the use of the electric light.

American Gas Light Journal, May 2, 83.

ELECTRIC LIGHT IN THE STREETS OF BUFFALO, N. Y.—The Brush Electric Light Company wants to get a slice of the street lighting in Buffalo, N. Y. On Thursday, April 12th, a committee of the Common Council considered the proposal of the Brush Electric Light Company to light portions of Seneca, Exchange, Elk, Smith and Sobieki Streets, and the Abbott road by electricity at 75 cents per night for each lamp. The company proposes to place the lamps not more than 400 feet apart, if a lamp was out from fifteen minutes to an hour, one half the price for the night is to be deducted; if out for an hour, the whole price to be deducted. This collection business is certainly refreshing.

Mr. James Adams said that if the lamps were placed 300 feet apart the company would only charge 63 cents per lamp per night.

Mr. George Fullerton, the Superintendent of the Mutual Gas Company, then addressed the committee and his figures clearly demonstrated that the lighting of the streets named by gas was much cheaper than by electric light. He figured as follows:

Seneca street, between Smith street and Buffalo river, 7,280 feet. Exchange street, between Smith and Seneca streets, 680 feet. Elk street, between Smith and Seneca streets, 6,720 feet. Abbott road, between Exchange street and Buffalo river, 2,600 feet. Smith street, between Exchange street and Abbott road, 3,000 feet. Sobieki street, between Exchange Elk streets, 1,870 feet. Total distance, 22,200 feet.

Electric lights, 400 feet apart (the maximum) 60. Each lamp per year of 365 nights, at 75 cents per lamp per night, $273.75. Per year for 60 lamps, $16,320.

Gas lamps, 140 feet apart (the maximum) 160. Gas consumed per lamp per year of 3,614 hours, at four feet per hour, 15,285 feet, making at $1.75 per 1,000 feet the cost per lamp per year $26.76; adding $3.04 per lamp per Cost of of 169 lamps per year, $4,084.40.

Cost of lamp-posts and lamps and setting them, $2,480.

Total cost of 190 gas lights per year, $7,672.40."

Gas cheaper than electric lights the first year, $8,251.60. Gas cheaper than electric light after the first year, $10,731.60.

His statement, however, failed to make any impression upon the committee, as they immediately resolved to report to the council in favor of contracting with the electric light company for lighting the territory in question at 75 cents per lamp per night.

LIGHTING THE SOUTHERN EXPOSITION BUILDINGS AT LOUISVILLE, KY.—A contract for lighting the buildings in which the Southern Exposition is to be held was entered into with the representative of the Edison Company for fifteen hundred electric lights, of a nominal candle power of 4,000 Edison incandescent of copper wire used and over 40,000 pounds, and, if stretched out, would reach 40 miles. It will take the labor of 100 men working steadily for one month, to install the plant. Fifteen dynamo machines will be required to furnish the current, and the cost of these alone will be in the neighborhood of $60,000. The power will be furnished by four Armington & Sims engines, and one large Reynolds-Corliss engine, the latter being provided by the Exposition Company. It is estimated that the latter being present lighting equipment will be fully $100,000. The grounds surrounding the buildings, as also the courts, will be illuminated by 75 arc lights; the usual 2,000-candle statement lamps will be illuminated by 75 are lights; the usual Exposition people had better put in the gas pipes too, for it is more than likely that "the bulb might slip."

ENTERED AT THE POST OFFICE AT NEW YORK, N. Y., AS SECOND CLASS MATTER.

THE AMERICAN ELECTRIC LIGHT COMPANY OF BOSTON.

A company, said to be organized under the laws of the State of Massachusetts, with the above name, has, according to the Boston papers, come to grief, and seems to be left in a wrecked condition with $16,000 debts and no assets, except "a fine stock."

The affairs of this company seemed to be decidedly mixed between parties from New York and parties from Boston, and it is needless to attempt to unravel its mysteries for the benefit of our readers. Highly respectables names cannot, of themselves, save any concern.

The three requisites to insure to electric lighting schemes it might be suggested that the business of lighting by electricity or by any other illuminant, when carried on in a legitimate way, and is entitled to respect; but when the popular cry of "lighting by electricity" is employed to promote schemes for floating stock, selling rights, and otherwise doing a kite-flying business, it becomes another matter, and it is a pity that the beauty of the pure electric arc, or incandescent loop, should be marred by having its name used for improper purposes. But how can it be expected that electric lighting should escape any more than gas lighting—for less not the good old-fashioned business of gas lighting had to endure the tribulation of having many a scheme, promoted under its name, which had no other backbone than interests for processes which, somehow or other, could never be made to work with satisfaction and profit after their removal from the nursery where they were born.

With many of these paienis there were "millions in it" before they were tried. So it is with other branches of business. If a company is organized to sell electric light on a business basis, and can get plenty of business at prices that will pay a profit, there is no reason why any one should not invest in it, if he has the money, and feels disposed to use it in that way. But there is no royal road to wealth in the lighting business, whether by oil, or by gas, or by electricity. Companies that are properly conducted, and sell a good article at remunerative prices, usually pay; but money cannot legitimately be made out of nothing. Stocks may be worked and manipulated for a while, but some one gets hurt in the end.

To those who propose to invest in electric light we would say, *invest in a business* and not in a scheme.

The whole business is very well covered with patents, and a strong and powerful combination has been made for the purpose of defending the essential patents from all infringement. It would seem from this that those who are disposed to do a legitimate business, in a legitimate way, here become fully convinced of the danger inherent in a multiplicity of interests working for the same ends, and that the wisdom of consolidation must appear if there is any truth in the old motto, "in union there is strength." Of course there is a great advantage in mutual protection; *how much* among value this advantage is worth remains to be seen.

The New York *World*, of April 28th, publishes the following—

"An important movement in electric lighting was consummated yesterday at the election of the representatives of the different companies to the new "pool-board." For some time the so-called Gaseous Company has been composed of the United States, the American, of New Jersey, Cons; the Brush, the Fuller, the Jablochkoff and the Weston. On Tuesday last, arrangements were completed under which the Edison joined the combination. The following gentlemen were yesterday elected as representatives: G. W. Hibbard from the United States; G. W. Stockley from the Brush; Leon-

American Gas Light Journal.

Electric Light at Newport, R. I.

A taxpayers' vote upon the following proposition was taken on April 10th, and resulted in its adoption by a majority of 295 in a total vote of 930.

"Shall the City Council be authorized to light Equality Park, Washington Square, Touro Park, and Bellevue Avenue with the electric light at a cost not to exceed six thousand dollars per annum?"

No definite statement is here made of the number of lights or the price per lamp.

Electric Light at Lafayette, Ind.

The Cincinnati *Commercial*, of April 17th, says that the Brush company have put their lights in operation in the above-named city. They have but one most and five lamps. The city contracted for two years. The light went into operation on the evening of the 14th, and caused quite an excitement among the people of the city. There is a wide diversity of opinion as to whether or not the light will prove a success sufficient to do away with gas.

The Electric Light.—Its Uses and Abuses.

The parties who have undertaken the task of furnishing the electric light in this city suffer a great many inconveniences. In the first place, it is asserted that the engine used at the company's headquarters is not of sufficient power to furnish the necessary light, as annoyance greatly complained of by customers. Very often it transpires that the light is entirely extinguished, and the only alternative left the customers is to use the gas—an expense entirely unlooked for. It often happens that light is not furnished for four or five nights during the month, but when the monthly bills arrive it is found that no reduction has been made for the nights on which no light had been furnished, a fact which causes a deal of trouble to both the consumers and the company. Winne & Co., being considerably bothered by the extinguishing of the light on occasions when it was most needed, notified the company to take out their lamps, as it was the intention of the firm to give up using the electric light. The company paid no attention to the notification, whereupon the wires in Winne & Co.'s store were cut by the firm, thus shutting off the supply. Other merchants who have been placed to a great deal of trouble by the antics of the electric light threaten to follow the example of Winne & Co., and it looks as if the electric light company will have a hard road to travel before the arrangements will work to the satisfaction of all its customers.—*Troy Observer*, April 17.

Electric Light Accident at Rochester, N. Y.

On the evening of the 30th of June, shortly after the electric lights were ignited, it was discovered that the roof of the building, No. 124 State street, Rochester, N. Y., was on fire. An extinguisher was immediately brought to bear on the flames, and the blaze was speedily suppressed. It was evident that the fire was caused by imperfect insulation of one of the wires of the Brush Electric Lighting Company, and, strange to say, no attempt was made to prevent a recurrence of the trouble. The consequence was that about an hour and a-half afterwards precisely the same thing happened. A policeman was summoned, and in his attempts to extinguish the flames inadvertently touched the wire and received a severe shock, as did also a man named Clark, who was endeavoring to assist him.

A reporter of the *Democrat and Chronicle* went to the scene of trouble with one of the employees of the Brush Company, and investigation showed that one of the electric light wires had rubbed against the edge of the roof, causing the insulating material to wear away, and the bare wire coming in contact in some manner with a telephone wire fixed the woodwork of the projecting cornice. Measures were at once taken to make the conducting wire secure.

American Gas Light Journal.

Electric Light at Akron, Ohio.

EXCHANGE HOTEL,
COLUMBUS, OHIO, March, 22, 1882.

To the Editor AMERICAN GAS LIGHT JOURNAL:

A few days ago I sent you a copy of the Akron (Ohio) Daily News, containing expressions of opinion by citizens of Akron adverse to the Brush tower lights in use in that place. Thinking a personal observation of the light might interest your readers I concluded to write to you. I went to Akron not so much for the purpose of finding what was the cost of operating the nine lamps (that has been pretty clearly demonstrated, I believe, to largely exceed the cost of the gas previously used) but to see how the lower system *lighted* the town. The sum of my observations is that the town cannot be said, as a whole, to be lighted at all. No gas is used for street lamps, and the oil lamps are burned only in parts of the town. The towers only give a light of practical value within a range of less than three short squares in the streets on which the lights are situated. The cross streets running into those on which the lights are situated are "as dark as Egypt," the electric light only illuminating the tops of the houses on one side of three streets. While the Brush lamps are brilliant at the burning point (painfully so to the eyes) the distance to which they will cast a good light seems surprisingly small, even when we remember that the ranges, in a direct line, of different lights are not directly proportional to their intensities, but only as the square roots of their respective candle powers.

To show how short the range of the tower lights is—at the intersection of Howard and Market streets is a wrought iron tower 208 feet high, on top of which are four lamps, said to be of 4000 candle power each; now, for a test of what this light can do. Desiring to know the exact three short squares from the tower on the same street (Howard) I could not see far enough in front of me to find whether there was a store crossing there or not (my eyes are good ones, 3} years old) and on the *fourth* square from the tower, and in a direct line with it, the oil lamps were burning—they *ought* to have been burning on the *third* square.

At the engine house there was one 4000 candle Brush lamp which threw a good light on the spot where I was standing with a friend on the sidewalk opposite the engine house. The shadow of the building extended over the sidewalk, across the way, and into the street a few feet. Now, although the street is rather narrow, on looking across it the shadow of the engine house was so black that we could not see the figure of a man, nor any other object, in the shadow.

From a short distance from the big tower light the shadows were extremely black. The light does not seem to diffuse at all. After the stop lights are out a footpad could lurk unobserved in any doorway, or behind any projection, and strike you down before you saw him. The shadows are so sharp that even within a short distance of the tower you cannot see the faces of persons coming towards you from the town.

A prominent manufacturer of Akron, whose name and character are widely and favorably known, in conversation with me pronounced the system for street lighting a "humbug"; and, although he uses one of their machines in his factory, operating it with the same engine that he uses to run his machinery, says he only put it in because he was too far away from the gas mains to get gas, which he would greatly prefer, as a modern price.

An old citizen of high standing laughingly remarked to the writer that the Brush people were "lighting" for smartness, and that it was always when the moon was about a week old, and its light sufficient to help out the electric light that they brought village councilmen and other inspectors to Akron.

As the expressions of all the citizens to whom I talked were adverse to the present system of lighting the town, I cannot think it will be very long until the sovereign voter will make himself heard, and Akron will abolish the present ghastly glare and return to her "old love," the soft, beautiful, diffusive, always reliable gas light.

Yours truly,

HARRY CALDWELL.

[September 30, 1882.]

THE STATIST.

HAMMOND ELECTRIC LIGHT AND POWER COMPANY.—Mr. Hammond writes in reference to an incorrect rumour, and states that the new construction which the company are busily at work in connection with the Brush system, but is first thereof.

CHELSEA ELECTRIC LIGHT AND POWER COMPANY.—At an extraordinary meeting a resolution was passed omitting clauses 10, 30, and 31, and making certain alterations in clauses 32 and 34 of the articles of association. The chairman explained the object of the alterations, which he said had been suggested by the Stock Exchange Committee on their application for a settlement. The first general meeting of the company was afterwards held. The company was formed with a nominal capital of £300,000, of which they had allotted £100,000 in fifty shares each, leaving £200,000 unissued. The directors' report stated that they had been engaged in the Chelsea Vestry Hall, he said, have completed the whole of the capital if they had obtained it. Besides their regular customers, they were receiving numerous inquiries from hardware merchants, decks, theatres, and private persons; in fact, no great were the demands that they had a difficulty in fulfilling all the requirements made on them. They had made applications to the vestries of London and all the various local authorities for permission to lay their wires in order that they might supply current who required the electric light, just as gas and water were supplied. The Board of Works had prolonged their contract with the company for lighting the Thames Embankment, and they had now given them permission to erect a much larger building on the Embankment, in order that they might have larger engine power there, and supply a greater amount of electric light. They had also taken a building on the Albert Embankment for the purpose of making their own meters. The meters were obtained from another company, who made them in France. They used to cost 7l. each, while they now cost 2l. They hoped by making them themselves to reduce the price, and have a profit equal, if not greater than they now had. They believed that when they made the meters themselves they would be able to allow a tremendous reduction in their present rate, as well as make them larger; and they hoped not only to supply them to their own customers, but also to the French company working on the same system as themselves. Since the formation of the company Dr. Jablochkoff had visited this country with a new patent maker, which they had purchased from him. It would be able to drive any small machine by electricity, and in itself it was a generator of electricity. In answer to questions, the chairman said that as soon as the company could manufacture the candles he had referred to. The time was not yet opportune for the formation of subsidiary companies, but when the proper time arrived they might grant powers for small towns and parishes. They were now making preparations for lighting the Gaiety Restaurant in the Strand. They believed their lighting of the Thames Embankment paid for itself, and they had given notice to the District Railway Company to cease lighting for nothing Charing Cross Station.

BRUSH ELECTRIC LIGHT AND COLONIAL ELECTRIC COMPANY.—The chairman, at the meeting held the company was formed on June 13th, and on the Monday following the applications for shares amounted to 24,452, which were all allotted. The object of the company was to acquire the patent rights of Mr. Edison for electric lighting, and to apply them in India, Australia, Ceylon, and the Australian colonies. They had received late negotiations for the formations of companies at the Cape and in New Zealand, and in the Australian colonies, and there was every reason to believe that the company would meet with success. The company having now been formally formed, the directors had no reason to make any report to the meeting, but he trusted that when the annual meeting was held they would be able to present a very satisfactory report.

SWAN UNITED ELECTRIC LIGHT COMPANY.—At the statutory meeting the chairman said it was too soon yet to say much of the prospects of the company, as electric lighting was yet in its infancy. He believed, however, there was a great future for the Swan light. This company possessed very valuable addition to their property in the right to make and use accumulators, without which it would not be possible to deal with electric lighting on a large scale. With reference to the threatened litigation between the Edison and Swan Companies, there could be no doubt of the character of the inventions concerned, and he thought it not unlikely that the companies would join forces rather than fight each other.

THE BIGHT WAY TO LOOK AT IT.—Evansville, Ind., wants to try the new "mast" system of placing the arc light. The Evansville *Journal* evidently does not think very favorably of the idea; and, in dealing with the subject, speaks as follows:

"The new contract, it is understood, proposes to substitute for the six towers, each 250 feet high, originally contracted for, 12 masts, each 160 feet high, similar to the one, according to the *Courier*, which fell with a crash in Cleveland and came near destroying both life and property. In other words, it is deliberately proposed now by the electric light company to exchange the towers, whose height and stability constituted their chief charm, according to the *Courier* and other champions of the system, for 12 masts, whose liability to tumble over and endanger life and limb they have fully conceded. Before councilmen consent to this change they will do well to hold two or three tests in mind. First and foremost, the city is in no financial condition to indulge in two systems of street lighting. The city already has a contract with the gas company which will hold good until the city is so well lighted for less money. The electric light company ought to be required to indemnify the city against all liability or loss by *reason of lackadaisy* of the gas contract before entering into any new contract. If the electric light people are so confident of the success of their system, they cannot reasonably object to giving such a bond.—This is business and common sense, not politics or jobbing."

ELECTRIC LIGHT IN WASHINGTON MARKET, N. Y. CITY.—The United States Electric Light Company have removed their incandescence lamps from the stands and booths in Washington Market. The reason given is that they were unable to supply the lamps. The company proposed to charge consumers at the rate of $2 per lamp per month, the lights to be charged for whether burned all the time or not at all. Several marketmen, among whom may be mentioned C. W. O'Brien & Co., Reynolds & Co., Sattler & Bauer, Thurnall & Co., Kay & Co., Kennedy & Co., in stating that at no time was the illuminating service rendered by the lamps comparable with that obtained with gas. It might be here stated that the incandescence lamps were in use in the market about two months.

ELECTRIC LIGHT IN BOSTON, MASS.—At the meeting of the Boston Board of Aldermen last week the following order was adopted:

Ordered, that the committee on lamps be and they are hereby authorized to contract with any responsible electric lighting company or companies, for furnishing the city electric lights, the cost of the same to be charged to the appropriation for lamps.

This order is making considerable stir, from the fact that two of the committee on lamps are interested in electric lighting companies in this city—the Brush and the American. A general interpretation of this order has been that it is to authorize the committee to light the entire city by electricity. Alderman C'Brien explains that the order is simply introduced to allow the committee to expend the balance of the appropriation made for electric lighting, amounting to $4,500.

ONE TWENTY-THREE FIELD.—A Boston (Mass.) paper states that one of the best testimonials as to the safety of the electric light for mill and factory Company. Of the concerns insured by them 82 are lighted wholly or in part by electricity, comprising 2,018 arc and 10,481 incandescent lights.

From all these lights only 22 fires have occurred from the following causes: Sparks, 8; water leaking or reeling flours, 5; water condensing on beams, 3; falling carbons, 5; other forms of cross currents, 2.

of interests in this direction could be effected that would probably result in a greater net gain to each than they now secure.

Notwithstanding all that has been done during the last few years to cheapen the cost and improve the quality of the gas, there is yet much that may be done, for our resources are far from being exhausted. We must be able to sell gas at a price so low that our consumers can afford to use it any and everywhere that light and heat are required; and just as fast as we make progress in reaching this point, just so fast will we lessen the ratio of capital to the sum cost, and with the possibilities before us of cheapening the cost of gas, if we do what is within our reach the day is not far distant when our sales will be doubled.

We have a great deal about oil gas, heating gas, water gas, etc.; but I have yet to be convinced that there is any water gas company in existence to-day that, laying aside the interest of the "patent process," or some special interest of the kind that someone has in it, but what could do better with coal gas, taking all things into consideration, than they now do. Water gas, as generally made, is practically prohibited by statute in some States, and should be in all. Whenever the poisonous nature of the gas is mentioned, it is silently ignored as being unworthy of a moment's notice. In fact, from the standpoint of water gas patents, one might infer that recent researches in chemistry had led to the discovery that carbonic oxide is not a poison; that all chemical text books were mistaken; that the aforesaid carbonic oxide is not only not a poison, but is actually a benefit to the gas. Gentlemen, we cannot afford to trifle with the health and lives of our customers by supplying a gas of such poisonous nature, when we can furnish an article that has not in its volume a quarter or a third of this poisonous element. The number of deaths that have occurred from the use of it since its introduction being more than has been known in the history of the business previously, is sufficient comment on that point.

Whenever any business is made successful you always find men who are quite willing to sacrifice personal motive and interest in other directions and exercise their philanthropic endeavors in serving the public in the same capacity, and the gas business is no exception to the rule. Probably most of you are aware that operations of this kind have been going on in various parts of the country for some time, promoted by several separate combinations or interests and their field of operations is not entirely outside of New England. The animus of some of these people may be imagined when I repeat to you a remark made to me personally by one who had a large interest in the class of patents, and who was gifted more with inwards than judgment. Said he, "All the gas companies in the country have got to come to me. I have got the money and the power to throttle the throat of every gas company in the country." Most of these gentlemen have a pleasing address, plenty of show of money and often have a way of explaining the matter so clearly to many members of municipal councils as to convince them that the public welfare can best be subserved by granting them the privilege of occupying the streets, and establishing a company to make gas by their patent process.

Members of this association should take it upon themselves to inform their directors of the operations these gentlemen are engaged in, and also to furnish the municipal authorities of their various cities and towns with such information as will tend to thwart the endeavors of these people to enrich their own pockets at the expense of the public, who are interested to at least an equal extent with gas companies. City and town authorities have only to study the history of all so called opposition gas companies to ascertain the results and effects in this and other countries, and to satisfy themselves that the only gain from such speculating schemes is to the pockets of the operators at the expense of every consumer of gas, as well as the city or town that is so short sighted as to allow them to dig up its streets.

In more than one instance have the efforts of directors of gas companies been seriously hindered by having to spend money to defend themselves against the schemes of speculators who have sometimes carried away large sums of money which might have been saved to the people in the price of gas, and at the same time the gas company has been left with an unnecessary expense of its capital. It is not improbable that these things will go on until it will necessitate action on the part of the State conferring to gas companies protection in their chartered rights and requires of them an annual report of their doings, and also restrict them within certain limits in their profits, as is the case in European countries to-day.

I am not sure that the time has not already arrived when gas companies should take the initiative in this matter, being guided by the experience of other countries, and proceed to secure such legislation in the several States as will effectually stop the operations of these speculators who, taking advantage of the ignorance of municipal authorities in regard to these things, often secure their aid to further their schemes. If our directors would properly inform themselves, take in the situation, and each New England gas company appoint a committee from its Board of Directors, say the president, a director or the engineer, with authority to act as he may deem to be for the best interest of the company he represents, meet and confer together, some united action could be taken, wise measures could be adopted, having for their object security and protection to both gas companies and consumers.

As I said before, having the experience of other countries to guide us, wise and judicious laws could be framed, which if enacted would give gas companies reasonable profits and a position secure from the interference of operators in so-called patent processes, and at the same time give consumers a feeling of satisfaction, which they do not now enjoy, of knowing that the profits of the business are not exorbitant as many consumers seem to think. This matter is worthy of your earnest consideration.

There are matters of interest which will, no doubt, be brought up in your discussions which I need not mention in this connection, as I have already taken up too much of your time, but I cannot let th's opportunity pass without again calling your attention to the aims and objects of our association, which to my mind are too much neglected. Must it be said that we as New England men are degenerating, that we are are departing from the standard and reputation of our ancestors? From the days of the Pilgrim Fathers down to the present moment, New England men have been identified with the prosperity and progress of almost every important movement and interest that marks our history. On into any State in the Union, you will find the work of the brain and hand of the omnipresent Yankee. Go into almost any country in the world you will find the product of his inventive genius and skill. Could you blot out at once all the machinery and improvements that has been developed from the brains of New England men you would perhaps see the mechanical history of the world. Shall it be said of us, of this New England Association of Gas Engineers, that we are untrue to the traditions of our fathers?

Must a single member of this association feel obliged to connect himself to some other association of workers in the same business before he can feel that the time and money spent in attending the meetings, have not been entirely wasted? We have the ability and the material in this association, which if properly used, would invest each meeting with such interest that each member would feel and know that he had lost something if he were unable to be present. Let each member bring to these meetings the same spirit and energy with which he prosecutes his own business at home, none would have cause to complain.

Many seem to think that a paper to be read before our association should be an account or a description of some wonderful invention or remarkable career of success that has been made; but such ideas are entirely erroneous. Let us have papers embodying the results of operations, experiments or trials which have resulted in failure. It will bring out the experiences of others in the same line, and oftentimes save some from spending money in doing the same thing. The efforts of your officers will be well nigh fruitless without your co-operation; with it the success of the New England Association of Gas Engineers is assured.

On motion of Mr. Stinson, a vote of thanks was tendered to President Slater for his very able and entertaining address.

(To be continued.)

The Electric Light Speculations.

The New York *Sun* of Feb. 8 published a notice of the capitalization of the various electric light companies which have made their appearance in this vicinity during the last three years. The notice also deals with the fluctuations in prices which have marked the dealings in this class of securities. It should be here stated that since this notice was published in the *Sun* the quotations of shares in the parent Edison concern have improved somewhat. On Feb. 19 a fair figure would be $400 per share. The notice is as follows:

The stocks of the electric light companies made their first appearance in Wall street about three years ago. The stock of the original Edison Company was the first that was dealt in, and it has sold at prices that have never been reached by any other. The shares of other companies speedily followed those of the Edison into the street. A most remarkable speculation in them immediately attended their advent. None of them have ever been listed by the Stock Exchange, and though most of them have been called in the room for dealing in unlisted securities, the transactions in them there have been small compared with the sales that have been made in the street. Those sales have been negotiated or made through what are known as outside brokers or brokers in unlisted securities. One or two of these brokers, notably Mr. A. J. Sapcrtas, have made a specialty of dealing in electric light stocks. Mr. Saportas has followed the movement in those stocks from its inception, and has dealt more extensively in them than any other broker. The speculation started with a boom. Prices, particularly for the Edison stock, fluctuated widely and rapidly. The memorable bull speculation that then prevailed in the Stock Exchange, as well as outside of it, may have been partly responsible for the initial movement in electric light shares. The most potent reasons, however, were doubtless general ignorance or understanding about the true value of the inventions and discoveries than being made

in electric lighting, and the mystery with which those developments were surrounded. Since then the several companies have been demonstrating what they are capable of doing, and the subject of electric lighting has been studied and investigated till prices for those shares have gradually drifted to figures that doubtless approximate their intrinsic value.

In the following resume of the market for electric light shares, the figures given are of sales that have been made through brokers. Both higher and lower prices may have been obtained at private sales.

The Edison Electric Light Company, the parent company and pioneer in the field, was originally organized with a capital of $100,000. This was increased to $105,000, and then to $200,000. The company owns about 51 per cent. of the stock of the Edison Illuminating Company, which was organized to use the Edison inventions in this city, and of the stock of the Edison Company for Isolated Lighting. The value of these holdings is taken into consideration in estimating the value of the shares of the parent company. When its capital was $100,000, its $100 shares sold as high as $5,700. Three shares sold at that price. The purchaser of these shares is reported to have sold them at private sale on the same day for $5,000 a share. The original seller paid $2,000 a share. He therefore made $6,100, and the second seller made $3,000. All of those transactions, it is said, took place in one day. One of the first transactions in this stock was the sale of five shares for $1,000, or $200 a share. On the day after this sale the purchaser sold two of the shares for $500 a share, thus recovering the amount of his purchase money for the lot. He afterward sold the three remaining shares for about $8,000, which was his profit on the venture. At times the price jumped up $100 a share in an hour. The son of the president of one of the largest corporations in the country sold twenty shares that cost him $3,000—that is to say, $100 a share—for $25,000, or $1,175 a share. The purchaser sold the stock shortly afterward for $1,575 a share. The stock is now selling at the lowest figure it has touched since it came upon the market, namely, $250 a share. A sale was made at that figure not long ago. The price has twice been offered by the borrower of the company's capital, as the increase in capital has been offered to the stockholders at par. At the present market value of the shares of the Edison Illuminating and of the Edison Isolated companies, it is estimated that the stock of the parent company is worth about $150 a share, merely as representing the interest of each share in the aggregate market value of the stocks held by the company.

The capital of the Edison Illuminating Company is $1,000,000 and the par value of its shares is $100. Fifty-one per cent. of its stock was given to the parent company for the Edison patents, which it is entitled to use exclusively in New York city. The company proposes to light the city by districts. Its first district is bounded by Spruce street, Park row and Broadway, and the East River. It has equipped an engine house in Gold street, not yet succeeded in furnishing any light to speak of, though it has about 7,000 lamps which have been lighted at times. The stock of this company has sold as high as $125 a share and as low as $30. The former price was reached before the company had got much of its plant, and the latter a few months ago. The last sale is reported to have been at $50 a share, and it is now offered at $50, $10 a share being bid for it.

The Edison Company for Isolated Lighting was organized with a capital of $500,000, which was subsequently increased to $1,000,000. The par value of the shares is $100. The object of the company is to furnish light to private buildings or establishments. Fifty-one per cent. of its stock is owned by the parent company, which has also issued to it for the patents and privileges. When the capital of the company was $500,000 its stock first sold up to $240 a share, and then as low as $175 to $180 is bid. The price at present, however, depends to an extent upon the number of shares offered or bid for. This is the only Edison Company that has paid a dividend. One of four per cent. out of the operations of the last year has recently been declared. Though the parent company has thereby paid a dividend, large profits have accrued to the stockholding company. Each year of new stock at par at times when the premium was very great.

The Edison Electric Light Company of Europe was organized about two years ago, simultaneously with the other offshoots of the original company. Its capital is $5,000,000 and the par value of its shares $100. It has a monopoly of the Edison system in Europe. Its stock sold soon after it came on the market at $165 a share, and has declined to $40. The present quotation is $10 bid, $25 asked.

The capital of the United States Electric Lighting Company is $1,500,000. Its shares, of the par value of $100 each, sold about three years ago at $300 per share. During the extreme depression in this class of stocks about six or seven months ago its stock sold at $85.50 a share. The last actual sale was at $125, and at present $130 is bid and $150 is asked. The company has just declared its first dividend. It is five per cent. in cash, but whether it is to be considered as an annual, a semi-annual, or a quarterly dividend cannot be learned.

The patents of the United States Company are used exclusively in the city by the United States Illuminating Company, which has a capital of $1,000,000, only one-half of which has been issued. The transactions in its stock have not been large. This last was at $102 per share.

The Brush Electric Company of Cleveland sustains practically the same relation as the Edison to several minor companies. It has a capital of $5,000,000 in $100 shares. The stock sold recently at $110, and it is said that it can be bought at that price now. The present bid price is $100. It has never sold below its par value. The company has paid quarterly dividends of two per cent. for three years.

The Brush Illuminating Company of New York uses the Brush inventions and system in this city. It furnishes, it is said, over 1,000 lights nightly in the up-town district, which it supplies at an average price of 80 cents a light per night. It began furnishing street lights to the city at 49 cents a light per night, but the price has been advanced to 70 cents. The cost to the company is said to be 50 cents. It is reported that the company will earn $100,000 net this year. The capital is $1,000,000, and the $100 shares have sold as high as $125, and about three months ago had dropped to $70. The current quotation is $100 bid and $110 asked.

The Brush Illuminating Company of New York owns most of the stock of the Brush Electric Light Company of New England, which uses the Brush system throughout the Eastern States. This stock is not dealt in, but it is supposed to be worth about $600 or more a share. The company has just declared an extra cash dividend of 50 per cent, making a total of 58 per cent. that it has paid within a year. The report is current that the New York and New England companies contemplate a consolidation.

The Fuller Electrical Company manufactures electrical machines. It has a capital of $670,000, of which $500,000 is common stock and $170,000 preferred. The par value of both classes is $100. The common stock has sold from $21 to $22 a share, and the preferred from $61 to $70 a share. Present quotations are $20 bid for the common, offered at $23, and $75 bid and $100 asked for the preferred.

The American Electric Light Company has been distinguished chiefly for the counter charges of fraud that some of its officers exchanged a few months ago. The company has a capital of $500,000 in $50 shares. Some of those shares have sold at $35. They are now offered at $4.75.

The Brush-Swan Electric Light Company is the last organized enterprise of this class. It combines all the Brush and Swan inventions, and uses electricity generated by the Brush process in the Swan incandescent lamp. The capital of the company is $600,000, and the par value of its shares is $100. Sales have been made at $150 a share, and it is now quoted at $105 bid and $150 asked.

For the common protection of their patents, all of the leading electric light companies formed some two years ago the Gramme Electric Light Company. The shareholders are the American Electric Company of New Britain, Conn.; the Brush Electric Company, the Edison Electric Light Company, the Fuller Electrical Company, the Jablochkoff Electric Light Company, and the Weston Electric Light Company. The stock has no marketable value.

While the prices that now prevail for the shares of most of the electric light companies are the lowest that have ruled, it will be observed that there has been considerable recovery in the case of those companies which have demonstrated their ability to make returns upon the money invested in them. Those, however, are few in number, and, with the exception of the Edison Isolated, are companies that furnish only the large lights that can be utilized chiefly for out door lighting or for the illumination of large buildings. The small light that is required for general in-door illumination has not yet been furnished for general use, nor has any return been made upon the money invested in its development and introduction. Where bills have been rendered according to some persons who have paid them, been larger than a gas bill would have been for the same amount of service. So far as speculation is concerned, however, the inquiry for electric light shares is, according to the best information, the same amount of service. So far as speculation is concerned, however, the inquiry for electric light shares is, according to the best information, increasing and the volume of the transactions larger as compared with three or four months ago, when trading with them was at a standstill. This, doubtless, is largely due to the first dividends recently declared by two or three of the companies.

AND WHAT WILL HAPPEN NEXT?—The Board of Aldermen of Brooklyn, N. Y., have calculated the people of that city by actually passing a resolution which will prove of great service. It is a rare matter to be able to say such a thing of any board of aldermen; but in the case of the Brooklyn board it is simply wonderful. At a late meeting of that body they decided to require the gas companies of the city to equip their meter-takers and collectors with badges. This step was taken for the protection of householders from sneak thieves, who, representing themselves as employees of gas companies, gain admission to houses for the purpose of plundering.

American Gas Light Journal.

Mr. Edison on Storage Batteries.

There appears to be one point at least on which our "own Edison" and those engaged in the manufacture, storage and distribution of gas have thoroughly agreed upon. This unanimity of opinion centers upon the idea that the so-called storage batteries, whereby electricity is to be delivered to consumers, already bottled up and ready for use—somewhat after the fashion, at present in vogue around New York city, of furnishing "bottled milk"—is a delusion and a snare, when commercially considered.

A representative of the Boston *Sunday Herald* called upon Mr. Edison, some time ago, with the object of ascertaining his views upon the electric light in general; and the outcome of the interview furnishes some very interesting reading. Mr. Edison, in considering the subject of "storage," made use of some plain language, and we reproduce some of his remarks, regretting that lack of space prevents us from giving the interview in full. In answer to the question as to what he thought of the utility and value of storage batteries, Mr. Edison said—

"The storage battery is, in my opinion, a catch-penny, a sensation, a mechanism for swindling by stocking companies. The storage battery is one of those peculiar things which appeal to the imagination, and no more perfect thing could be desired by stock-swindlers than that very self-same thing. In 1870 I took up that question, and devised a system of placing storage batteries in houses connected to mains, and charging them in the day time, to the thing patented in 1879 (I forget the date of the patent) but there is nothing in it. I rung all the changes on it. My plates were prepared like Plante's. The method of preparing them for charging is more tedious, but it is better than that of Faure, after preparation. You know the first storage battery was sent from France to Sir William Thompson, who was at first astounded by it. He was asked to endorse it, consented and took a retainer; but on investigation he became convinced that there was nothing in it, and returned the retainer to the French company. The fact is, the more he investigated the more he found out the fallacy of the whole business. On account of what Lalouchere calls a swindle, this secondary battery has been used by the ass companies in England. One company alone, on the strength of an accumulator and an incandescent lamp copied from mine, by one George Lane Fox, floated subsidiary companies, whose aggregate capital was over thirty millions of dollars, and immense sums were paid by these companies to the parent company for rights. Within the last few months the bubble has burst, the shares, upon which $25 have been paid, are offered at $2, and their prospectuses as to the value of the accumulator and the right to the incandescent lamp of Mr. Fox, it appearing, from the proceedings before Mr. Justice Chitty, that another company had a right to the lamp, and this company acknowledged that it was a piracy of the Edison lamp, and were paying royalty to the Edison company for the right to use. The indictment was in Justice Chitty was brought by a stockholder in a subsidiary company to cause the return of his subscription on the above account. The judgment was in his favor. This was the great Brush electric light bubble, in which millions were lost, and caused the now celebrated article of Lalouchere. One of the leading spirits in the bubble is in this country at the present time attempting to do the same, but Carlyle's saying about thirty millions of fools probably didn't apply to foreign countries.

"Scientifically the thing (storage) is all right, but commercially an absolute failure, as one can imagine. You can store it and hold it; but it is gradually lost, and will all go in time. Its efficiency, after a certain number of charges have been sustained, begins to diminish, and its capacity and efficiency both diminish after a certain time in use, necessitating an increased number of batteries to maintain a constant output. Owing to corrosion of the sustaining plates of the battery, the effect of local action and other causes, so many to enumerate, the yearly depreciation of the battery is not less than 30 per cent. of its first cost, if used daily. The facts are that there are two or three companies that have been organizing subsidiary are light companies throughout the country for some time past. In this arrangement the parent company made money by selling machinery, etc., to the working companies, but the latter companies are not making money; and have nearly ceased giving new orders. Now the parent companies, finding the sell for machinery slacking, have come in with their secondary batteries. They now make this statement which is the cleverest thing I ever heard of. Here, gentlemen, you have a large investment in machinery, etc., for furnishing light, but are not making any money out of it. Now, we have something by which you can utilize your machinery. You can work day and night, and can do more than made in the day-time for incandescent lighting, and in the night have your plant for are lighting direct. That sounds good and fair, does it not? The board of directors discuss the offer and think it a good thing. Then they conclude to go into it. You probably know what the wisdom of the average board of directors amounts to.

"I will tell you where the fallacy in this arrangement lies. It consists in the fact that the cost of batteries to store this extra electricity that could be produced in the day-time would be twice as much as the station that produces it; so that, if the company has already invested $100,000, and agree to utilize their machinery in the day-time, by the addition of storage batteries, they will find that to carry out their desires it will cost them $200,000 for the batteries. I will guarantee that not one board of directors in a hundred will see it, and the parent concern will not tell them of it until after they have purchased. It seems to be natural with boards of directors that if there is a wrong way to do a thing they will surely do it that way. Well, they have purchased the storage batteries, of course, at a cost of $200,000. On that investment, at the end of the first year, they have a depreciation of thirty per cent. To save themselves they will have to earn interest on their investment. They must earn enough to meet the extra depreciation on their plant running through the day, and will have to spend double the amount in coal to obtain the same output from batteries, for the reason that they interpose between the source of energy and the light a thing in which there is a loss both in charging and discharging, and a loss while standing, and that loss increases as the battery gets older, after a certain maximum is reached.

"The maximum of a storage battery is about fifty per cent. You get the maximum of current when you utilize the full capacity of the battery, the same as in a steam engine, where, if steam is admitted for the full stroke, 50 per cent. of the steam or power is wasted, but you obtain the maximum power from the engine; but this is also the minimum of economy. Hence to get the proper economy, engine builders only take one-third to one-fourth of the maximum power from their engines, but this adds to the investment, which is compensated for by the saving in economy, which more than pays interest on increased investment. When they say that 90 per cent. is obtained from the battery they tell you what is scientifically true. They say they get ten lights of 16 candles each per horse power of current. Now, this is true and untrue. If you get a horse power of current from a battery 2 will give you 10 lights of 16 candles; but to get that you have to put all loses through the battery, through the wires, through the dynamo, and all that. They start off with a horse power indicated in the engines. A certain amount of this is taken to move the engine and dynamo, and a certain amount is lost in the dynamo to convert power into electricity, because no machine is perfect; a certain amount must be lost on the wire connecting the station with the secondary battery; another amount is lost in charging the battery, due to its resistance and imperfection as a mechanism; another amount is lost during the interim between charging and use; another portion will be lost in discharging the battery through the lamps, and still another amount will be lost in the wire connecting the battery to the lamp. So that your horse power will dwindle down until it will give you only about three lamps; whereas, if you worked direct you would probably get six lamps."

American Gas Light Journal, July 2, 1883.

HOW THE ELECTRIC LIGHT AFFRAIS TO SOME PEOPLE IN ALBANY, N. Y.—Albany does not appear to be overjoyed with her electric lighting experiment, as witness the following from the Albany *Times*:

"Under the new charter of the city of Albany, the board of contract and appportionment may enter into a contract for lighting the streets of this city for a term of 999 years, or longer if they shall see fit. All other contracts are limited to two years, but this is entirely without restriction. Already gas has been entirely superseded in the streets, only two lamps being retained, on the theory that this will be regarded as fulfilling the contract of the city with the gas company, which does not expire till next fall, when very likely the theory will be tested by tedious and expensive litigation. The electric light shines from the river front to the intersection of Madison and Western avenues. In the winter the service is excellent; in the summer, owing to the height of the poles on which the lights are placed, much of the illumination is cut : f by the foliage of the trees, and as a whole, the city is thus practically little better lighted than it was by gas. In the vicinity of the pole there is too much light, but in the shadow the darkness is dense. The electric light is also expensive. It will cost the city $6, where gas cost $1. This is a great increase. Had the proposition been made to put up five gas lamps, where there was only one before, a perfect howl would have been heard; but had it been carried out, we should have certainly had a much more even and probably quite as satisfactory a light every way. But Albany has the electric light, and differing from almost every other, if not every other city in the United States, she has paid for the outfit. For once, this conservative old town has gone too fast. The electric light is an experiment. Other cities which have partially adopted it find that they can not afford any such extravagance. For instance, it being rumored that in Cleveland, Ohio, which, next to Albany, has been cited as a city in which the new light had made the most rapid advance, it was about to be abandoned, the editor of the *Times* made inquiry of the mayor of that city, who replied as follows:

CLEVELAND, May 21, 1883.

DEAR SIR: Cleveland does not do much in way of electric lighting—and then present contracts expire, will probably d scontinue, if for no other reason than the lack of funds; the system costing the city about five times more than gas. Very respectfully yours, JOHN H. FARLEY, Mayor.

"The other day we published extracts from the very sensible veto message of Mayor Manning of Buffalo, returning, without his approval, a resolution providing for the extension of the electric light through certain streets in that city, and based on the ground, among others, that they could be lighted with gas at 60 per cent. less.

"It will be said, of course, that 'Albany wants the best;' but she will have to pay accordingly. She is in pretty deep already, but is to be lumped that she will not go in over her head, as also surely will, if the electric light contract is relet for a long term of years. The excuse will be made that we have bought the 'plant,' and it is too late, nothing can be done, and it doesn't matter whether the next contract is for one or twenty. Not so. The elephant is a great asset, and it took a good deal of money to pay for him; but let us not be our hands so we can not shop his bond off, if his appetite become too ravenous. Despite our city charter, no shrewdly worded as to allow of this gigantic jobbery, the board of contract and appportionment are city, and thousands of dollars may be lost to it by a long contract. It should be removed yearly, at most. No one can tell what twelve months will bring forth in the way of inventive age. Experiments may yet demonstrate that the electric light can be produced at one-tenth the present cost; and then how rash and ridiculous would appear a contract under which the city pays yearly $200 a lamp."

MAXIM LIGHTS FOR LANCASTER, PA.—It is stated that the Maxim Electric Light Company are to erect 250 lights for purposes of street illumination in Lancaster, Pa. Sixty of the lamps are to be in position by the 10th of August, and the remaining sixty are to be ready by September 10. The Lancaster *Intelligencer* says we must learn from the experience of other places; well, if they will not be taught, let them "pay the piper."

The Manufacture of Patent Fuel in France.

Commercial Agent Gifford, of Nantes, has submitted to the Department of State an interesting account of the manufacture of patent fuel out of the coal dust which was formerly rejected as worthless, and which is now burned in immense quantities in France as coal bricks. The millions of tons of coal dust, the waste of our mines, renders this process of some interest, as the subject has long occupied the attention of large consumers of coal. After importing the dust from Wales and paying duties and cost of landing, the manufactured article in France costs $4.42 to $4.87 per ton. It is claimed, besides its advantages for manufacturing and locomotive purposes, that it is superior to other coal for domestic purposes. For some years the Orleans Railway Company has bought annually 60,000 tons. The cost in the United States, it is claimed, would be less.

The process of manufacture is given as follows: "It is extremely simple. The coal dust is mingled with pitch (*brai suberac*) derived from coal tar, and the mixture poured into cups attached to a belt, each cup containing just enough material for a brick of the size desired. The belt in six movement passes this material through a chamber where it is exposed to hot steam, which fuses the two substances into a homogeneous mass. This is poured by the descent of the belt into moulds, where it is subjected to an enormous pressure by a hydraulic press, or by machinery act in motion by a steam engine. The brick is square in form, its thickness being about one-third of its other dimensions, and, as manufactured here, weighs 5, 10, or 15 pounds."—*Coal Trade Journal.*

Public Lighting in New York City.

The officers designated in section 1 of chapter 478 of the Laws of 1879, met in the office of the Mayor, at 12:30 P.M., on Monday, April 17, 1882.

All were present viz.:

Hon. Wm. R. Grace, Mayor; Hon Allan Campbell, Comptroller; Hon. Hubert O. Thompson, Commissioner of Public Works.

The minutes of the meeting of March 27, 1882, were read and approved.

The Secretary presented the following report:

BUREAU OF LAMPS AND GAS, March 28, 1882.

DEPARTMENT OF PUBLIC WORKS,

To the Honorable the Mayor, the Comptroller, and the Commissioner of Public Works:—

In compliance with the resolution adopted on the 27th inst., directing the Secretary to examine and report upon the several proposals received on said date, I respectfully submit the following report:

First—As to gas lamps. * * * * *

The rates are the same as now paid all the gas companies under the existing contracts.

The United States Illuminating Company propose to light by voltaic arc lights, of 2,000 candle power, at 70 cents per night for each lamp, the streets and parks shown in the following statement, and was the only bidder for furnishing electric lights to same. The same streets and parks, however, are included in the proposals of the New York, Manhattan, and New York Mutual Gas Companies.

District bid for by the United States Illuminating Company, with the estimated number of electric lamps stated to be necessary to light the same; also the estimated number of gas lamps which can be displaced:

	Number Electric Lamps.	Gas Lamps Displaced.
Broadway, from Battery Park to 14th street	22	256
Battery Park	12	144
City Hall Park	10	110
Fifth avenue, from Washington Park to 14th st.	8	43
Washington Park	12	152
Total	94	705

—or one electric lamp to seven and a half gas lamps.

1 electric lamp per night	$0 70
7½ gas lamps, at $17.50 per year, 4.8 cents per night is	0 36
Excess per night for 1 electric lamp over 7½ gas lamps	$0 34
Or 1 electric lamp per year at 70 cents per night is	$255 50
7½ gas lamps per year at $17.50 each is	131 25
Excess per year for 1 electric lamp over 7½ gas lamps,	$124 25
Or, 94 electric lights 1 year at 70 cents each per night is	$24,017 00
705 gas lamps at $17.50 each per year is	12,337 50
Excess for electric lights for 1 year	$11,679 50

The Brush Electric Illuminating Company presented two bids. One was for furnishing voltaic arc lights of 2,000-candle power (French measurement) for streets, and clusters of six 2,000-candle power lights for two parks, at the rate of 70 cents per night for each 2,000-candle power on the streets and parks shown in the following statement, and it was the only bidder for electric lights on those streets. The Manhattan, Metropolitan, and New York Mutual Gas Companies included these places in their respective proposals.

District bid for by the Brush Illuminating Company, with the estimated number of electric lights stated to be necessary to light the same; also the estimated number of gas lamps which can be displaced:

	Number Electric Lamps.	Gas Lamps Displaced.
Broadway, from 14th to 34th street	18	99
4th avenue, from 28th to 34th street	17	
Park avenue, from 34th to 42d street	25	294
4th avenue, from 42d to 59th street	16	
Madison avenue, from 27th to 59th street	33	186
5th avenue, from 14th to 59th street	41	264
8th avenue, from 14th to 59th street	46	300
14th street, from 4th to 8th avenue	9	53
23d street from 4th to 8th avenue	9	44
34th street, from 4th to 8th avenue	10	44
42d street, from 4th to 8th avenue	10	59
57th street, from 4th to 8th avenue	11	41
59th street, from 4th to 8th avenue	11	31
Madison Square, 1 pole, six lights, equivalent to 16 street lamps	16	141
Union Square, 1 pole, six lights, equivalent to 16 street lamps	16	85
Total	272	1,632

—or one electric lamp to six gas lamps.

Or for each portion of those spaces and such number of lamps, at said price, as may be prescribed by the Gas Commission.

1 electric lamp per night	70 cts.
6 gas lamps per night at 4.8 cts. each	28.8 "
Excess per night for 1 electric lamp over 6 gas lamps	41.2 cts.
Or, 1 electric lamp per year at 70 cents per night	$255 50
6 gas lamps per year at $17.50 each	105 00
Excess per year for 1 electric light over 6 gas lamps	$150 50
Or, 272 electric lamps 1 year at 70 cents each per night	$69,496 00
1,632 gas lamps 1 year at $17.50 each	28,560 00
Excess for electric lights for 1 year	$40,936 00

The other bid of the Brush Company was for lighting the High Bridge and its approaches by from 16 to 32 electric lights, more or less, at $1 each night, but they were not furnishing the steam, or $1.50 each lamp if steam is furnished by the company. On this bridge and its approaches are 24 gas lamps bid for by the Harlem Gas Light Company at $19.50 each per year.

The following shows the district now lighted by the Brush Electric Illuminating Company:

	Number Electric Lamps.	Gas Lamps Displaced.
Broadway, from 14th street to 34th street	53	
5th avenue, from 14 street to 34th street	16	253
14th street, from 4th avenue to 5th avenue	1	
34th street, from Broadway to 5th avenue	3	
Union Park, 1 pole, 6 lights, equivalent to 16 street lamps	16	16
Madison Park, 1 pole, 6 lights, equivalent to 16 street lamps	16	
Total	75	434

In the new bid the company reduce the number of lamps now on Broadway by five, which would make the total number of lamps in present district 70, against 434 gas lamps displaced, or 1 electric light to 6.2 gas lamps.

70 electric lights one year at 70 cents each per night	$17,885 00
434 gas lamps one year at $17.50 each	7,595 00
Excess for electric lighting in present district	$10,290 00

The total result of the United States bid and the first Brush bid is as follows:

266 electric lamps one year at 70 cents each per night	$62,033 00
2,337 gas lamps, one year at $17.50 each	40,897 50
Excess for electric lights	$20,635 50

THE STATIST.

HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY.—At a meeting of the Board of directors, held on August 16th, it was resolved to call up the remainder of the capital. The directors have since issued a circular giving formal notice in reference to the calling-up of the remaining £2 10s per share. The calls are as follows:—£1 5s. payable September 21st, and £1 5s. payable January 1st next. It states that, in spite of the prevailing very profitable use made of electricity has this year been gradually giving place to public favour and, on the threshold of another lighting season, the directors are rejoiced with so many applications for installations on hire that there is prospect of supplying very profitably the share capital which hitherto they have refrained from calling up.

PILSEN, IRON, AND GENERAL ELECTRIC LIGHT COMPANY (Limited).—The annual general meeting was held on Wednesday, the Earwaker, W. Barwise presiding. In moving the adoption of the report, the chairman observed that the most material point was with regard to the necessity of the call of 10s. a share which the directors had made. When the company was formed, the directors fully expected to derive from the sale of concessions, not only in the United Kingdom, but also in the colonies, a large amount of capital, which would have enabled them to carry on their manufacturing and other operations without calling on the shareholders. With this expectation they reduced the amount on allotment from £3 to £2 a share. Circumstances had, however, changed almost since the birth of the company. The expectation of an early sale of concessions had been deferred, and there had been a revulsion of public feeling, not only with regard to electric lighting companies, but also with regard to electric lighting generally; and the action of Parliament, when as it might have been in the interests of the public, had necessarily been a check upon the operations of the electric lighting companies. After congratulating them on the provisional orders which they had obtained, he alluded to the dismissal of the two petitions which had been presented for winding-up the company, and strongly condemned the manner in which they had been promoted. Within the past few days a very important contract with a Government department of them had been nearly completed. They were negotiating with respect to other contracts, and he hoped by their next meeting that they would be able to report that they were doing a profitable business.

THE STATIST.

GUERNSEY ELECTRIC LIGHT AND POWER COMPANY.—At the meeting the chairman said the company having only been formed in May, where had been but a short time to do anything beyond organising. A report had been prepared, according to which there were applications for 23,147 shares, and 20,000 out of 27,597 were allotted among the shareholders, leaving 3,597 shares to be allotted before a settlement could be obtained on the Stock Exchange. There was no doubt they would be readily accepted for among the shareholders. The directors had disposed of a concession for Scotland, and there were negotiations.

American Gas Light Journal, July 16, 1883.

The Electric Light in Liverpool.

The manner in which the Corporation of Liverpool intend to avail themselves of their power to light by electricity the streets and public places of the city has been at length settled, at least to the extent of the first "experimental experiment" in the most important thoroughfares. Advertisements requesting tenders for the proposed lighting having been inserted in all the leading newspapers, local and otherwise, the Corporation eventually found themselves in possession of two proposals—from Messrs. Siemens Bros. and the British Electric Light Company respectively—to which their choice was necessarily confined. Messrs. Siemens Bros. asked £5200 for lighting the selected district from sunset to sunrise for a period of twelve months, with an extra allowance of £2250 for fixing and removing the apparatus.

The British Electric Light Company offered to do the work, in their own way, for the same period, for £2805 10s. The latter tender was accepted by the City Council at their meeting on Wednesday last, and the contractors are to be ready to light up by the 1st of March. The price to be given for the electric lighting is nearly twice as much as is now paid to the gas company for the present service, which includes several Sugg's and Bray's powerful burners, and a number of four feet per hour ordinary street lamps. The city engineer, in his report on the electric lighting proposals, remarks that if the necessity for increased illumination is to be taken for granted, five sixty 2000-candle electric lamps proposed to be fixed by the British Electric Light Company will, in terms of illuminating power, be considerably cheaper than gas. This is certainly one way of putting it, but it is not the right way. In the first place we all know that the light of thousands of candle power vary readily from electric lighting contractors, when they know perfectly well that their lamps will never be put into a photometrical test and tested to a tenth part of a candle, in the same manner as gas is examined daily.

Would the contractors for supplying Liverpool with lamps of 2000-candle power consent to a fine whenever their light fails to yield this power, or even half of it? Again, the proposed 20 lamps are to supplant 216 gas lamps, and we are grievously mistaken if it is not found that some portion of the roadway lying midway between these new lights will be no better illuminated than it would have been had the same value been given for the gas left to experience to decide, for it may be supposed the Corporation will take steps to assure themselves that they are getting the full value for their money.

A striking peculiarity of the electric light, often remarked in other cases, is brought prominently forward in the engineer's report, the difference between lighting the selected district from sunset to midnight, and between sunset and sunrise, is only about £160 for the year. In other words, it only costs this amount to keep the generating machinery and carbons going for the few extra hours per night; but, of course, at the same time the full amount of illumination must be kept up, for with electricity there is no medium—it is either in full blaze or nowhere. This fact illustrates the disadvantageousness of the arc-light, and at the same time suggests what might be done with gas if the cost of brilliant lighting is to be insisted only during the few hours of darkness in which it is really required, and no more than the night only drives. As Mr. Clement Dunscombe, the city engineer, remarks, the illuminating power of the proposed electric lights is on the contractor's own valuation, but in a sense, considerably cheaper than that supplied by gas in the same thoroughfares; but it may be suggested that the power of a lighting medium expressed in the gross, and its power of illuminating other objects, are very different things. If the corporation of Liverpool are content to trust the lighting of their streets to a string of light-beacons of the height of those afore named, they will find out what little difference means, and may eventually learn that they will find out what possible power, in close proximity to the object desired to be seen by its aid, is quite as useful as a light of ten times the reputed power a hundred yards off, and carefully hooded up out of the way.—London *Journal of Gas Lighting*.

American Gas Light Journal.

Electric Lighting Companies in England.

That "all is not gold that glitters" is shown from the proceedings in one of the English courts, on which the *Journal of Gas Lighting* makes the following comments.

"A crushing blow has fallen upon the Brush concessionary companies, the probable effect of which will be to break up the entire fleet. On December 8th Justice Chitty had before him an application by a shareholder in the Great Western Electric Lighting and Power Company to have his name struck off the register of proprietors, and the money paid in respect of his shares returned, on the ground of misrepresentation in the prospectus. We have already commented in these columns upon the nature of this insecurity, which consists in claiming an exclusive license for the Lane-Fox incandescent lamps, whereas there was really a prior assignment of this valuable property to another and independent electric lighting company. Several of the concessionary Brush Companies fell into this blunder, and all of them are now in trouble on the same score. We have already observed how, in consultation with their constituents, the Directors of those similar concerns practically agreed in describing the Lane-Fox patents as worthless, and the representations in the prospectus relating to them as consequently unimportant. The same opinion was used on December 8th before the learned Judge in the Chancery Division, but with most disastrous results. With strong common sense, as well as with legal acumen, the Judge decided that it was not competent for persons who had framed a prospectus which from being to end had recommended as one of its leading attractions this particular invention, to afterwards say, for the purpose of upholding their prospectus, that the invention was of little or no value, and therefore not a chief attraction in the document in question. The application was granted with costs; the sums paid for the shares to be returned to the applicant by the Company. As these shares were probably allotted at par, and are now at a hopeless discount; and as there are numbers of other disappointed speculators ready to seize a chance for hanking out upon similar terms, the condition of the Brush companies altogether is not to be envied.

"While the subsidiary Brushes are almost in *articulo mortis* the great parent concern is supposed not to be free from embarrassment. At the end of August last the company declared, an interim dividend of 10p per cent.; and it was also announced that there was a great reserve of cash in other quarters. Yet in the brief space of four months after this high water mark had been recorded, a call of £3 per share has been made, which is calculated to amount to £81,000.—The quoted value of the partly-paid shares still keeps at a very respectable figure; but it is asserted, by persons ably well-informed parties, that 'the market is only sustained by the process of underpinning on the part of those whose present interest it is not let it down with a flop.'"

THE STATIST.

BRUSH ELECTRIC LIGHT AND POWER COMPANY OF SCOTLAND.—The directors state that the present was the first ordinary meeting of the £300,000, in 60,000 shares, of which the first 30,000 were issued to vendors for the purchase of the Brush patents for Scotland. The remaining 30,000 were offered to the public before the shares had been made in the most equitable manner possible. The applications for the concessions for having been granted. The directors had also received a quotation by the Stock Exchange Committee, a proceeding, in fact, which would depend on the work they obtained in Scotland. Applications for tenders for their work were continually coming in daily. They had been successfully delayed by the low prices obtained in Scotland, which entirely prevented the liquidation of the old company, which was now completed. In reply to questions, the chairman stated that they now were lighting the Waverley Station at Edinburgh, and that they had tendered for the lighting of the Tay Bridge and Forth Bridge stations. They also hoped shortly to do work for the mills. The managing director stated that they had paid £12,000 in cash and £40,000 in shares for the patents. He thought they had acted wisely in not proceeding too fast.

ELECTRIC CABLES, SYNDICATE, AND APPARATUS MANUFACTURING COMPANY OF SCOTLAND.—The chairman stated that this was the statutory meeting called in compliance with the act. They were now in possession of the patents in connection with the set. They were in factory ordered, and they hoped to be able to begin in a few weeks to manufacture dynamos and lamps. Their prospectus came out when the forces concerning the electric light was at an end, and they had not been so successful as had been hoped in getting their capital taken up; but they considered it wise to go to allotment, and in the meantime to go on with a capital which, though comparatively small, was sufficient. They were waiting with a well-organised manufactory to take advantage of the time when the best electrical machinery would be before the public.

METROPOLITAN ELECTRIC LIGHT AND POWER COMPANY.—The chairman at the special meeting said he would simply move that the resolutions agreed to at the former meeting, amending the articles of the association so as to bring them into harmony with the regulations of the Stock Exchange Committee, be adopted. He understood a settlement had been granted, and after that resolution was carried there would be a quotation. The resolution was carried, and the first statutory meeting was then held. The statement put had not much information to afford. Up to the present time the work in hand had been that of organisation and preparation for the work which would most successfully be before it when the dark days came on. The application for shares numbered 282,000, of which there were duly allotted 100,000 out of that number there had been 9100 shares allotted to persons, who as well known as a competent organiser, had been appointed managing director. With regard to the Bill before Parliament, he looked upon the compulsory sale clause as unobjectionable. Replying to questions, it was stated that the directors had a most substantial interest in the company's shares. The only contract [illegible] went in answer to the Camberwell Vestry's advertisement was one from this company.

[Jan. 8, 1880
NATURE

Mr. Edison publishes through the columns of the *New York Herald*, an elaborate and detailed account of his labours with his new form of electric lighting. Minutely describing the course of his studies, Mr. Edison says that he has made the discovery that the carbon filament of a small piece of paper is the best substance for incandescent lighting. A piece of cardboard, known in the trade as "bristol," is cut, with a suitable pencil, into strips in the form of miniature horseshoes, about 2 inches long, and one-eighth wide. A number of these strips are placed in a metallic mould, separated from each other by tissue paper. The mould, after being well covered, is placed in an oven, where it is gradually exposed to a temperature of about 600° F., so as to allow the volatile portions of the paper to pass away. The mould is then removed to a furnace, kept there till it attains almost a white heat, and subsequently allowed gradually to cool down. On opening the mould, the charred remains of the cardboard must be taken out with great care, in order to prevent them from falling to pieces. They are placed in a small globe and attached to the wires connecting the generating machine. The next step is to extract the air, by means of the pump, from the globe; that being accomplished, the globe is sealed, and the lamp is ready for use. It should be observed that the new lamp requires no complex regulating apparatus, such as characterized the earlier effects. In fact, Mr. Edison finds that all previous labour in regard to lighting has practically wasted, and furthermore, that electricity can be regulated with absolute reliability in a manner precisely similar to that in which the pressure of gas is now produced. The system now adopted by Mr. Edison in connecting the wires admits of a given number of lights being extinguished without affecting those of other lamps. In the same way as we would direct a certain number of gas burners and permit others to stay on, a supply from the source, the electric light can be obtained or shut out. From the description now given it appears that the apparatus primarily used by Mr. Edison was in the shape of a large tuning-fork, constructed in a manner that both ends would vibrate when placed near the poles of the great magnet. Experience has demonstrated the impracticability of that apparatus, and it became necessary to perfect for other uses. Our experiment was made after another, which had the tendency to lead gradually to the adoption of the system now employed in the governing machine, and which Mr. Edison terms the Faraday machine. It is briefly described thus:—Two upright iron columns 2 feet in height, and 3 inches in diameter, covered with coarse wire, and resting upon a base, form the revolving between the poles, is a cylindrical armature of wood, wound parallel to its axes with fine iron wire. The cylinder is made to revolve rapidly between the magnetic poles, and by means of a belt, driven by an engine, strong currents of electricity are generated in the wire surrounding the armature, and these currents are carried along the wires to the electric lamp.

[Jan. 8, 1880
NATURE

We learn that Mr. Edison is attempting to construct a portable electric lamp which shall, requiring the constant battery employed to generate the current, be no larger than an ordinary moderator lamp.

American Gas Light Journal.

Gas vs. Electric Light in Down-Town Stores.

A correspondent of the *Sanitary Engineer*, who signs himself "X.," makes the following communication to that publication:

Dear Sir:—Perhaps the following statement about the comparative cost of the Edison lamps and gas in a printing establishment (E. P. Coby & Co.) in this city, may be of interest just now, when the public is waiting, with some anxiety, the outcome of the effort to supplant gas by incandescent lamps in down-town stores.

In the establishment in question, the Edison lamps were put into the counting-room, first floor, on trial, to get a basis on which the cost could be afterward adjusted, and for this first month's trial the lights have been free. Within a few days, however, the company have sent out a statement of the amount of light given between certain dates, and the values of it on the basis on which hereafter they will charge their consumers, viz., 81 per 1,000 candles, which, according to the company, is about equivalent to gas at the present rate—$2.25 per 1,000 cubic feet. This, however, does not seem to be the case, at least with this establishment, as the following facts will indicate.

There are seven of the Edison incandescent lamps in the counting-room, of the ordinary size in down-town stores, to replace five gas burners. Owing to defects in the carbons, which have usually left one of the lamps useless, it has been necessary to light one or sometimes two gas burners in addition to the electric lamps. Under these circumstances, a statement is rendered by the Edison Company for the period from October 10 to November 13. Total amount of light furnished was 12,245 standard candles, for which, had the company charged their proposed price of $1 per 1,000 candles, the cost would have been $12.25. Messrs. E. P. Coby & Co. estimate that, taking both cloudy and fair weather together, the lamps have burned possibly five hours on an average daily.

At about the same time that statement was received from the Edison Company, the Mutual Gas Light Company rendered their bill for gas used in the press room and composing rooms. Connected with one meter are 25 six-foot burners on the two floors, and also the one or two which are used in the counting room. Of this number 22 are regularly lit, including those in the counting room, and burning on an average 1½ hours per day. The gas furnished by the Mutual Company, as appears from the weekly statement in the *Sanitary Engineer*, has an illuminating power of 25 and upward. The price of gas is $2.25 per 1,000 cubic feet, and the bill for the burners enumerated, from October 23 to November 22, was $10.85—representing a consumption of 4,600 cubic feet of gas.

Now, assuming that 6 of the 7 electric lamps were always in good order and lighted during the 5 hours per day when artificial light was necessary, the case would stand thus:

Six lamps, 5 hours each, = 30 hours per day; 23 gas burners, 1½ hours each, = 34½ hours per day.

Number of days from October 10 to November 13, 34; total hours of closing lights for that period, 1,020.

Number of days from October 23 to November 22, 30; total hours of closing lights for that period, 1,035.

Cost of 1,020 hours, electric lamps, $12.25; cost of 1,035 hours, gas, $10.85. Add to the latter the cost of the 5 lights which were burned in addition to the electric lights, and the total cost of gas would be $12.50. Thus the difference between the cost of light given by the two systems is but 25 cents in favour of the electric light. Add to this the fact that the electric lights are free from the annoyance of heat, and the fact that the electric lights are free from the annoyance of heat, and the fact that the electric lights are free from the annoyance of heat, and

Jan. 1, 1885]
NATURE

THE *Times* correspondent describes a visit he made to Inspector Mr. Edison's new electric light at Menlo Park. Two of the lights had been burning continuously for ten days without injury to the batteries, and enchanted horsecars in the little place of which furnishes the light. Candlepower, he states, seems sufficiently steadily, successfully emulating quite rough usage, such as dropping, shaking, turning the current on and off thousands of times, and raising the intensity of light to that of 200 candles. Of all the wonders he saw, however, Mr. Edison will put about 800 lights at Menlo Park, while the inventions immediately go into practical operation in New York city. The globe containing the horseshoe is exhausted to one-millionth of an atmosphere by the Sprengel pump, measured by the M'Leod gauge. By successfully dividing the electric current Mr. Edison gets individual lamps of 16-candle power, each lamp having its own resistance. Light is turned on or off, and the current regulated with the same ease as gas is, while the current can be transmitted on wire as small as No. 26. The central regulator contains an even current, while the meters accurately measure the supply furnished to each consumer. Mr. Edison feels that the best generators are of five to seven horse power, each one-horse power maintaining eight lamps. Each lamp costs about one shilling to manufacture, while a supply equivalent to 10,000 feet of gas can be produced for twopence or less. Mr. Edison maintains the cost of furnishing light thus—the consumption of 1 lb. of coal in a steam engine will maintain eight to ten lamps one hour. Mr. Hilliard's system also furnishes electric power for small industries, such as running sewing machines. Mr. Edison's light is bright, soft, mellow, regular, free from flickering or pulsations, while the observer gets more satisfaction from it than from gas. Mr. Edison lights at Menlo Park, therefore, will be a source of much interest to the scientific world, making it available for every lighting purpose for which gas is used.

[March 27, 1879.
NATURE

THE Select Committee of the House of Commons appointed to inquire into the subject of the lighting of towns by means of electricity, and to which the Liverpool Lighting Bill was referred, has continued to go into the question, settle the principle, and then leave the thirty-four private Bills which ask for powers to light by electricity to be dealt with by the regular Committees of the House of Commons. The inquiry will consist names on the 21st inst. As the evidence will be lengthy and the committee will probably report late in the Session, it is expected that no powers will be granted this Session for lighting by electricity.

THE Werdermann light was tried by M. Becquerel in his lectures on electricity, delivered at the Conservatoire des Arts et Métiers on March 19. This apparatus, which will be tried very shortly in Paris, has been introduced into France by Dr. Cornelius Herz. Mr. Werdermann has arranged round the chair of the professor and himself with the utmost regularity every time they were lighted. The opinion of M. Becquerel was very favourable indeed; he has witnessed the experiment of a steadier source of light, of exceptional brilliancy in the flame. He reserved the question of cost in comparison with gas, and confined himself to making a comparison between Werdermann and the competitors. M. Jules Jamin, perpetual secretary of Sciences a system of his own, which has been described in the *Comptes rendus*, and will be tried by the Jablochkoff Company. Other systems are said to be preparing so that the partial failure of Lontin is giving rise to a renewed electric light agitation in Paris. The members of the Municipal Council have determined, to give fair play to any rational experiments.

As the result of the experiment of lighting the Holborn Viaduct with the electric light, it has been found that the cost is twice and a half less than of gas, while the illuminating power is seven times greater, whilst the former decided not to renew [illegible]

Dec. 17, 1883.

American Gas Light Journal.

HARTFORD (CONN.) WILL NOT TRY THE "ARC" LIGHT.

Some short while ago a proposition was submitted to the local authorities of Hartford, Conn., by the Hartford Electric Light Company, which had for its object the illumination of the city's streets with the "arc" light. The proposal of the electric lighting company was to supply any number of lights that the authorities might deem requisite; such lights to burn from sunset until daylight, and to be charged for at the rate of 65 cents per light per night. The subject matter of the proposal was referred by the Hartford Board of Council to the Board of Street Commissioners, with instructions to report back to the former body as to the desirability and feasibility of entering into such a contract. The Street Commissioners reported that they deemed it inexpedient, at the present time, to go into any extended use of the electric illuminant, owing to the great cost of the same; but suggested that, by way of experiment, a certain number of the lamps be erected in prominent positions of the city. In the opinion of the commissioners, it was adjudged that one electric lamp would take the place of four gas lamps, and concluded their recommendations by saying that, "An actual trial will be the only way of demonstrating the power of the light, and proving its practical value for this particular use."

Appended to the report of the Commissioners was the following resolution:

"*Resolved*, That the Board of Street Commissioners are hereby authorized to establish such numbers of electric lights about City Hall square, on Bushnell park, and in parts of Main, State, Allyn, Trumbull, Pearl, and Asylum streets, as they shall deem requisite, not exceeding, in the whole, 20 lamps."

It was not to be expected that Mr. John P. Harbison (who is a member of the Board of Aldermen) would give a ready concurrence to the passage of this resolution, and he did not. Moreover, he came prepared with figures and statements showing why such a course should not be pursued, if due attention were to be paid to the best interests of the city's treasury. He noted how the proposed electric lights, at the rate of 65 cents per night, for 320 nights (estimating 35 nights out of the 365 as being sufficiently illuminated by the moon) would cost $214.00 per light, as against $139 per light for gas, at last year's rates, in accordance with the statement made by the Street Commissioners that one "arc" light would displace four gas lamps—an annual difference of $2,500 in favor of gas, even for this initial attempt at installing 20 lights in central portions of the city. Another thing that Mr. Harbison could not understand was why the city should be charged 65 cents when the same arc lights were already furnished to business establishments at 40 cents. A probable answer to this objection might be found in the reply that the latter are calculated to burn only until midnight, whereas the cost for the proposed city lamps was based on an all-night service. Mr. Harbison further said that, in the course of his inquiries on the subject, he found Boston (Mass.) was paying but 67 and 56 cents per night for an all-night service, and very pertinently propounded the question, why was it that Hartford was asked to pay 65 cents for an article that was being supplied by the same electric light company in Boston at so much lower figures. Mr. Harbison also warned the Council that the time was close at hand when public opinion would require the erecting of laws making underground electric conductors obligatory upon all those engaged in the supply of electricity for purposes of illumination, arguing that it would be unwise policy to embark in a business, the leading features of which would soon have to be changed. He further cited the fact that the gas company was a Hartford corporation, managed and controlled by Hartford capital, and had always been willing to do the fair thing by the Hartford authorities, as testified by the numerous voluntary reductions which it had made in the selling price of gas.

When the question, as to the indefinite postponement of the resolutions to enter into the contract recommended by the Street Commissioners, was placed before the Council, the arguments adduced by Mr. Harbison evidently had the effect of convincing the members that this was the wiser course to pursue; and the motion to indefinitely postpone was carried by the requisite majority.

The rate of 1875 and 1870 mark the third stage in the organic life of gas companies, and seems to have definitely settled the system adopted in London. A series of clauses in these acts define minutely the conditions under which an increase of capital will be permitted, the manner of using the reserve, etc.

The entire financial control is placed in the hands of an auditor of accounts, who must be a competent and independent person appointed by the Board of Trade. He is the possessor of very considerable powers. What over papers or documents he wishes must be furnished him; twice a year he has the right to prescribe the manner in which the accounts must be kept; no dividend can be declared until the accounts have been approved by him.

Testing the quality of the gas belongs to the Gas Referees, a sort of supervising commission also appointed by the Board of Trade, and consists of three competent and impartial persons, one of whom must have a practical knowledge of and experience in the manufacture of gas; they direct the manner to be taken for testing the quality, the degree of purity of the gas, etc.

The ordinary gas furnished must have an illuminating power such that a burner consuming 5 cubic feet per hour will yield a light equivalent to that furnished by 16 sperm candles, 6 to the pound, and burning 120 grains per hour. These conditions are somewhat different from those prescribed by the act of 1860; the chief difference consists in the illuminating power, determined in the number of candles, which is increased from 12 to 16, or 33 per cent. In reality, the increase in the illuminating power required is far greater than 33 per cent., because the standard burner used in 1860 was inferior to that adopted in 1868, which, with the same gas and the same hourly consumption, gives a superior light—the difference equalling 2 candles.

The standard burner used in the photometric tests is Sugg's London Argand, which was the burner used by the Gas Referees under the act of 1868, and has since been officially adopted at the conclusion of a report from the Gas Referees in July, 1871.

It will be of interest to note what the illuminating power of London gas is as compared with that of Paris, which is used as the standard for France.

In London, with a consumption of 141.5 liters (5 cubic feet) in the standard burner—Sugg's London Argand—a 16-candle light must be produced.

In Paris, with a consumption of 105 liters in the standard burner (Bengel), designated by direction of Messrs. Dumas and Regnault, the intensity of a regulating carcel must be obtained, or a light equal to 9.6 candles.

If the London and Paris burners were identical, or, at least, if they were gas under the same conditions, we would come to the conclusion, as the result of a single ratio, that 105 liters of London gas would produce a light

$$\text{equal to } 16 \times \frac{105}{141.5} = \text{or, } 11.8 \text{ candles,}$$

and that the same consumption of gas in Paris, giving only 1 carcel or 9.6 candles, the ratio of the standards would be $\frac{9.6}{11.8}$, or 81 per cent. The standard of gas in Paris would therefore be 81 per cent. lower than that of London; in other words, the standard of London gas being 16 candles, that of Paris would be equal to 16 candles × 0.81, or 12.96 candles. Such would be the result if the whole question were to be determined by calculation only.

This method of establishing the inferiority of the one over the other would not be accurate, because the London standard burner uses the gas to better advantage than the Paris standard; the kind of burner has, therefore, an undoubted influence on the result; and not to take this into account would be to commit a very material error—an error of the same kind that we would commit if we were to compare two grees of different illuminating standards; for instance, the Bengel burner with one gas and Ville's butterfly burner with the same gas. In that case we have what we would term to consume 105 liters of standard Paris gas in the first instance, and 127 liters in the second.

In this connection, then, the only conclusive experiments are those directly and carefully made. Professor Leclanc, tester of gas for the city of Paris, after making several experiments at the Paris municipal laboratory, embodied them in a report to M. Huet, Deputy Commissioner of Public Works, and gave, as the result of his labors, the following comparative statement: 141.5 liters (5 cubic feet) of Paris gas burned in a Bengel standard burner produced a gas equal to 14.7 candles: the inferiority of the Paris gas was thus proved to be only 1-12th, or about 8 per cent.

In experimenting at the same time with the photometer, Dussen's system, on the same principle as the official photometer of London, on several different occasions the Paris gas was found to be of a standard close to 16 candles.

There is only one other point that remains to be made clear—the value of

1. From the suburban companies only 14-candle gas is required.

the English candles in carcels. We have admitted all over that the value of the candle was $\frac{1}{9.6}$ carcel, or 0.1033 carcel. This is the value given by Schilling, which is quite close to that of $\frac{1}{9.5}$ carcel, or 0.1052 carcel, as given by Mr. Sugg, of London, and constantly used in England in comparing with French units. This value of the candle can largely be regarded as a fixed standard. As a result of tests made at the Exposition of Electricity in 1881, it was found that the number of sperm candles equivalent to a carcel varied from 8.8 to 9.5 for still-recent samples of the candle type. We learn, also, from a report presented in 1880 to the Board of Trade, by an English commission of which Professor Williamson was one, that candles taken from two different packages of the same make varied from 14 to 15 per cent. Recent experiments made by M. Mounier, operating upon 36 candles, showed still more remarkable variations. For instance, from 0.120 carcel to 0.102 carcel for the equivalent of a candle—quite a difference. Besides this there has been discovered a variation of 1.287 cascels in the consumption of 6 cubic feet per hour in the London standard burner, which corresponds to 12.2 candles, reckoning the candle equal to 0.12 carcel (the average of 36 experiments on 14); it will correspond to 14.9 candles, reckoning the candle equal to 0.103 carcel, Sugg's value.

It is difficult, in view of such variations, to speak with certainty on the average of a small number of experiments; we ought to await repeated trials, specially made at London with Paris appliances, and, notably, with the same kind of photometer, before we can say it is a fixed fact. We believe, however, that we are not far from the truth in admitting, *provisionally*, the approximate value of 14 English candles for the illuminating power of Paris gas as compared with London gas of 16 candles.

The pressure of gas ought to be at least equal to 1 inch of water (25.4 millimetres) from sunset to midnight, and 0.10ths of an inch (18.24 millimetres) from midnight to sunrise.

With reference to its purity, the gas furnished should be entirely free from sulphuretted hydrogen; the tolerance permitted in the act of 1860 is no longer permissible.

Some time during the week succeeding each quarter, the chief inspector sends a report to the Corporation, to the Metropolitan Board, and to the company, setting forth the illuminating power, the degree of purity, and the pressure, as established by the daily tests.

The before mentioned acts of 1868 set forth and establish the penalties incurred by the companies when the gas furnished does not meet the requirements in the illuminating power, as well as in the pressure and purity.

The above is a very rapid sketch of the general system under which three of the four great gas companies of London operate; the fourth Company (the London Company), which is the least important, remains under its old system with the Gas Light and Coke Company, as regulated by the act of 1860.

[To be continued.]

Opinion of Prof. Henry Morton as to the Practicability of Placing Electric Light Conducting Wires Underground.

In a late issue of the New York *Daily Times* there appeared the following communication, from the pen of Professor Henry Morton, in regard to the above-named subject. The Professor says:

In considering what should be done or left undone in reference to the raising of wires to supply electric lights in the streets of New York several questions present themselves as requiring answers before a decisive conclusion can be arrived at. What is the present extent of the business involved? What advantages or inconveniences do actually exist, or have been proved to exist, in the present systems during the two or three years of their past use? What remedies have been suggested, and what effect would the application of these remedies have upon the continuance and extension of these uses of electricity? What light does experience in Paris, London and elsewhere throw on this subject? What possible dangers or inconveniences have been suggested as likely to be encountered, though not yet experienced, and what probability is there that these anticipated dangers will ever be realized?

In the first place, let us consider what is the present extent of the use of electricity conducted through the streets of the city of New York. In the first place, we should observe that there are three general systems of distribution now in use:

First—The underground low tension system of Edison, used exclusively for incandescent lamps, each of which gives a light about equal to that of one gas burner.

Second—The medium tension aerial system, used by the United States Illuminating Company for incandescent lamps arranged in series.

Third—The high tension aerial system, used by the United States, the Brush, the Fuller, and other companies for arc lights.

[October 14, 1882.]

THE STATIST.

AUSTIN AMERICAN ELECTRIC ILLUMINATING COMPANY.—The chairman observed that it would be superfluous for anyone to enter into details of the working of a good deal that the Board was doing for establishing the business of the company, in the present state of the money market. The prospectus of 25,000 ordinary shares had been subscribed by the public. By a modification of the arrangement with the vendor, he had accepted for the patents transferred to the company £27,000, instead of £35,000, in cash, on account of the total sum of £50,000 agreed to be paid to him. The balance he had accepted in shares. The company possessed the Brush and Lane-Fox patents for Austria and Hungary, and the Brush patent for Germany. Considerable progress had been made in the Austrian and German kingdoms, where no patent laws at present existed. So far, however, as concerned their chief market in America, they were not yet in a position to carry on business in any other country. They had satisfied themselves that the Brush system was the best adapted for Austria, Hungary, and Roumania, for which the Brush system was suitable, and Brush lights were already in use in several considerable towns in Austria. Austria and Roumania contained together a population of over 42 millions, and assuming that on a rough percentage to allow for distance of electricity, a revenue of £1 would be derived for every £5 per head of population, the company would be receiving a large revenue when the working of the system of electrical distribution should be in local hands. In the opinion of the board, the profits of this company should take one third of the whole power in the first instance, and afterwards contractors and manufacturers in the different countries should be encouraged to form companies for the establishment of the systems of distribution which they believed would result from their pioneering. A committee of the Board, consisting of himself and two directors, had returned from a tour in Austria, Hungary, and Roumania, where they had been met by a most flattering general reception, and by every arrangement to engage in the Roumanian the committee had had several interviews with the Ministers, and given the company's prospectus to light up exceptionally well-to-do winter palaces and the grounds of his summer palaces at Bucharest. For this reason, which he mentioned, the directors were of opinion that it would be advantageous to the company to raise at this juncture a loan with which another company would be held.

LARGOMERSINO ELECTRIC LIGHT AND POWER COMPANY.—At the annual meeting the chairman stated that from that the company's rent had been proceeding very satisfactorily. The lighting of the Emiliani Theatre, the contract for which they took from the Municipality, was a loss. It was supposed that the working expenses would be 40 per cent, but that had not proved to be the case. The lighting, however, was a good advertisement for the company, and the annual loss had not been reduced from £700. It was about £500. Soon after the formation of the company, feeling that the time was favorable for establishing additional lighting and power for the moment, they turned their attention to manufacturing purposes, and to supplying installations in various places. The installations of the Casalino had gone on at their works on the Albert Embankment, and they were making them for cheaper and better than they were supplied by the French company. Their electricians had carried out many successful installations. At first there was much profit from the electric work, but they were now able to reduce the expenses day by day and to increase the profits. The only obstacle between them and the Board and Meyrlebone Vestries, which had at first refused to use the electric light, had been removed, and they (when he was told this if they got the business contracted for. The Board of Trade, as much money as they wanted would be supplied to them. However, in opposition to the wishes of the Board directed, a provisional order for the whole of the parish and the Swan Company's installation at the Paris authorities had made a new contract with the French company, paying them double the previous rent. The report referred to their works which had been carried on for the company, and they were asked to undertake. They could supply four or five times their present supply. They could supply four-fifths of the whole of the Metropolitan Board's work. With regard to the Swan Company's installation, it should have been shown to have been £300, not £2,000 as supposed, however, had been carried in the accounts of the company. The depreciation of the Swan Company's works, the worth of work, of which they had done about £2,000 worth, and which they had decided to leave £20,000 of their business leaving £ per cent. The directors intended for the future to take no remuneration till the company had earned a fair dividend. A long discussion followed, the general opinion being apparently contented that if expenditure had been on too large a scale, having regard to the capital of the company, the fault was not in the direction in fixing £2,000 for the year, for fees were criticised by several speakers, some of whom argued that the fees were criticised by several Mr. Hay, and that the right course to take was to wind-up. The vote, however, was strongly opposed by other speakers, who maintained that the company was solvent, and that the preliminary difficulties having been now surmounted, it would be unfair to wind-up. The Board of the company, it was stated, was to meet in a few weeks to consider the matter, when a resolution would be proposed.

[November 4, 1882.]

THE STATIST.

BATTERY ELECTRIC LIGHT AND POWER COMPANY.—In moving the adoption of the report, the chairman stated to the meeting that the accounts were not quite in such a form as he was in a position to give information to a small meeting. Many grave difficulties had arisen in connection with the application of the light. They had, however, been making satisfactory progress. They had sent out to India, and the East various electrical appliances to the value of nearly £40,000. That was up to the end of September. The chief part of their expenditure had been for as lighting. They had now established contracts in India for as much as £4,000, which was very small compared to what it would have been had they not been interfered with by the Government, who had prevented them from carrying on their works. They had now a satisfactory contract with the Municipality of Bombay, and at the present moment they were doing an amount of street lighting which, he thought, it would be difficult to find elsewhere. Contracts for two years had also been entered into with the towns of Berwick and Surat for street lighting, which they were now successfully carrying on every evening. He thought the directors might take credit for the small amount of expense incurred—£2,000. The call of £1 per share, which did not come into the present accounts, had been well met, and the money derived was being spent on the inauguration of their manufacturing scheme. They had made an arrangement with the Indian and Oriental Electrical Engineering and Works Company, whose batteries they now possessed the use of throughout the whole field of their operations. The report was then unanimously adopted; and at a subsequent extraordinary meeting certain alterations were made in some of the articles of association of the company, principally to meet the requirements of the Committee of the Stock Exchange.

[November 11, 1882.]

THE STATIST.

RIVER PLATE TELEPHONE AND ELECTRIC LIGHT COMPANY.—The directors have obtained a circular to the shareholders, with information as to the company's position and prospects. These are reported to be very satisfactory, the subscribers already secured in Buenos Ayres and Montevideo numbering 600 and yielding a total income of £12,228, which would enable the full dividend of 8 per cent. on the preference shares to be paid. As it is sound there is ample room for the profitable employment of further capital, it has been decided to issue a further 2,750 shares of the pre-ferred shares, existing shareholders having the option of taking them at par, £2 10s. per share to be paid on application and the balance on allotment.

THE STATIST.

AUGUST 21, 1882.

THE TIMES.

ELECTRIC LIGHTING.

TO THE EDITOR OF THE TIMES.

SIR,—It will scarcely be necessary for me to call your attention to the fact that the electric lighting, to bear out Sir Joseph's Paul Gotch, Mr. Martin's-le-Grand, will be illuminated by means of the Edison-Swan system, the supply of electricity being derived from the company's central station on Holborn-viaduct, at a distance of about 1,000 yards.

Installations are also being made in America by the principal firms of Edison and Swan, and by the Edison-Swan Company, and with the electric light having been laid down in the streets and in many private houses, offices, and everything being on the most complete scale. The electrical works have been of a most satisfactory nature, and during the past week in Regent-street by the Edison and Swan Company, a display has been made in the streets and in many of the houses and offices in the Hanover Square district, which was most successful, and was illuminated by the Edison-Swan electric light. The electrical engineering profession will be present.

I am, sir, your obedient servant,

ARNOLD WHITE.

The Edison Electric Light Company (Limited), Secretary, Colonna-street, Queen Anne's-gate, August 20, 1882.

A Difference of Opinion as to Cost of Electric Lighting between Mr. Lane Fox and "Engineering."

We published in our last number a criticism, by *Engineering*, upon certain glowing predictions of Mr. Lane Fox, made in his lecture delivered before the Royal United Service Institute. Mr. Fox thinks that *Engineering* hardly does him justice, and sends the following letter to that publication, in which he attempts to justify the statements made by him at the Institute. We also republish what *Engineering* says in answer to Mr. Fox's latest communication.

To the Editor of *Engineering*—Sir: In the "Electric Lighting Notes" of your last issue, you say, in criticising my lecture at the Royal United Service Institution, "In the first place, taking his own data we work out the cost for him, with coal at 20s. per ton, to be rather more than a halfpenny instead of a farthing." In the same way you might have worked it out, "taking my own data" with coal at 40s. per ton, and then you would have found the cost to be a little over a penny; and further with coal at 4s. per ton (the actual price of good coal delivered by rail in Glasgow) you would have found, always taking my own data, that the cost was a little under half a farthing. But taking the price of coal as the average rate throughout the kingdom, as I have taken it, you will find that my estimate of a farthing is not so far out.

Next you say that "An ordinary gas jet costs one-fifth of a penny per hour." I have put it at a farthing. Well, let that pass. You go on to say that "to-day there would be a difficulty in getting a supply of incandescence light at the price of gas." You might, indeed, have gone further, and added that with perfect truth that there would be a difficulty, and a very great difficulty, in getting a supply at all.

Finally, you say, "We wish that Mr. Lane Fox had been more explicit with his audience, and had furnished reasons which would have enabled us to share his sanguine anticipations." If you had read my lecture before criticising it, you would have found that your wish might have been gratified, for, indeed, the chief object of my lecture was to indicate "the possible directions in which future reductions is to be looked." My reason for thinking that we have not arrived at a final stage in electric lighting, and that it is what it comes to, is simply that we have not yet had any opportunity of testing electric lighting on a large scale by a properly organized system of low tension distribution. When such systems are established on a scale similar to those of gas, as I hope and believe they will be before long, I have no doubt that you, in common with the rest of the world, will be able to share my "rosy anticipations."

I am, sir, your obedient servant,

HENRY G. LANE FOX.

[In the lecture we ventured to criticise last week, we find that Mr. Lane Fox crystallizes his convictions on the subject of electric lighting by incandescence, in the following sentences: "An ordinary gas jet is equal to twelve candles only, so that for the same price twelve times as much light can be produced by electricity as by gas." We used not repeat the substance of our criticism, but we may say that Mr. Fox has, at most, but one supporter in argument it by a few distinctive made from careful estimates prepared by responsible engineers. Mr. Lane Fox has obtained all his results by placing his figures too favorably for electricity and too unfavorably for gas. The foregoing it will be seen that the various deductions stand as follows, the first two substantiated by careful and detailed figures, the third resting only on vague and general statements so far as appears from Mr. Fox's lecture.

	Cost of Incandescent Electric Light.	Cost of Gas to give Equivalent Luminous Duty.
Simmons	.149	.156
Cooke	.134	.140
Lane Fox	.0208	.260

—Ed. *E.*]

Bituminised Bricks.

The London *Builder* states that, in a recent issue, the *Deutsche Bauzeit.* ung called attention to an experiment in street paving in Berlin. Bricks of the dimensions of 8 by 4 by 4 inches (in the quality of the usual so-called Klinker bricks, and therefore) have been employed which have been impregnated with asphalt by a patent vacuum process. By this mode of treatment, after the expulsion of air and water has taken place, the bricks absorb from 15 to 20 per cent. of the bitumen, and the porous easily destructible substance is changed into a tough elastic mass, said to be capable of resisting pressure and concussion in an exceptional degree, and resisting the ingress of moisture. The bricks are then laid upon a concrete foundation, six inches in thickness, by means of hot tar.

The traffic at the point in question has always been heavy, so no less than 1,000 light vehicles per hour are said to cross the spot chosen for the trial, in addition to 1,300 tram-car journeys over this portion of the roadway. No

Statist, Nov. 10, 89.

THE STATIST.

BRUSH MOTIVE POWER ELECTRIC LIGHT AND POWER COMPANY.—An extraordinary meeting the chairman stated that a small number of shareholders—60 out of 500, and representing only 140 shares—had taken advantage of what they alleged to be a technical misstatement in the prospectus of the company, and had requested them for the return of their money. A friendly and large shareholder, however, who they might have noticed, had a petition to submit to the company, but that petition was less on desire whatever that the company should be wound-up. He only rose for the purpose of saying that he would support it. 19 shareholders alluded to having any private letter the rest of the shareholders, supposing that the statement in the prospectus turned out to be material, and the money was ordered to be returned to them. It had been stated that the object of the meeting was that the company was going to buy for their directors an exclusive concession for the Anglo-American Brush Corporation's patents outside and for the Lane-Fox lamp. It was not, and could not, be done in this way, and the exclusive right in the very valuable concession of the Brush dynamo machine. It was, however, very hard to say how the word "exclusive" came to be used in their prospectus as applied to the right to the Lane-Fox lamp. He did not know how it occurred that, the Anglo-American Brush Corporation had not mentioned the fact that Mr. Lane-Fox had given a license to the British Brush Light Company to use his lamp; but it was clear that the Brush Midland Company could only use that lamp upon terms with the British Electric Light Company in their district. It was a very curious fact that on the Board of one, if not more than one, of the subsidiary companies the word was used "exclusive" as applied to the Lane-Fox lamp, there were directors who were also directors of the parent Brush Company. He did not think that the directors could be supposed to know that such a license existed. What legal opinion they had taken about the word "exclusive" the Company or any one else he could not tell; but they might rest assured that if the company went to law to settle the question, the necessary steps should be taken with that object. It was to be clearly understood that the Lane-Fox lamp was not paid for with very valuable consideration for the use of the Brush dynamo machine; they paid nothing whatever for the use of the Lane-Fox lamp, and perhaps it was owing to the fact that the mistake as to the use of the word "exclusive" in connection with it had escaped the notice of the many solicitors through whose hands it had passed before it was passed. What they had to consider was whether they had been misled, was whether they had been injured from the want of the exclusive interest of the license for three months, and they might. To consequence of the proceedings which had taken place in this attention, there were two courses open to them—either to accept the loss or costless business. If they were to go into liquidation they would have a certain amount of assistance—say to the value of £2,000—and their present assets would go to the value of £1,000 cleared from the parent Brush Company. He, in fact, if they were to go into liquidation, getting assistance to forward sensible proceeding, the proceeding would be suicidal. The prospectus was issued in the fields of fact, but they had to realize only upon its value in actual work for their results, and in that period they had got to go through the advertising, the shareholders, the solicitors, the expenses they had incurred in making installations in several places, which they had felt obliged to do by way of advertisements. They had successfully fighted up the town of Chelmsford with the very best and also some very good business in addition to this. Brighton, for instance, contracts—at Oxford Street, at Nottingham and at Leicester two. If they threw up the sponge, liquidation, there could be no doubt that they would be able to realize £1,000 cash, in his opinion, to pay them a very fair dividend. If, however, they could not do that they would pay a dividend they would not be able to pay a dividend if they concluded by carrying the following resolution, which he moved, having heard the statement of the chairman as to the position of the company, is of opinion that the interests of the company should not be sacrificed, notwithstanding that some of the company should have demanded the return of the proceedings of the shareholders towards the directors of the company, and therefore re-pellion." In answer to a question, the chairman stated with regard to the opposing shareholders referred to, that if the worst came to the worst, they would have to pay them, and declared it carried, with one dissentient.

HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY.—An extraordinary general meeting is convened for the 15th inst., to consider resolutions for amalgamating with the company the Yorkshire and Sheffield Companies and Warwickshire Brush Electric Light and Power Companies, and the undertakings known as Hammond, Thompson, and Lees (Limited). The directors will also ask for authority to create and issue 10,000 deferred shares of the nominal value of £2 each, on the terms of the agreement already approved by the Hammond Company, and authorized to be carried into effect with the Ferranti Company. In the circular convening the meeting it is stated that the agreement with the Yorkshire and the Birmingham Companies provides for an amalgamation of the two companies, the Hammond Company forming their rights on the shares they hold in the Yorkshire and Birmingham Companies, and also agreeing to allot and issue to the Yorkshire and Birmingham Companies their shareholders fully paid £2 shares of the Hammond Company, in the proportion of one fully paid-up £2 share of the Hammond Company for every six £2 fully paid-up shares in the Yorkshire and the Birmingham Companies. The agreement with the Ferranti Company will provide for an amalgamation with the Hammond Company, by consideration of the issue to the Ferranti Company of 7,200 ordinary shares of the Hammond Company of the nominal value of £2 each, to be issued as fully paid-up, and 10,000 deferred shares, to be issued as fully paid-up, of the nominal value of £2 each, and which will only be entitled to dividend after 5 per cent. has been paid on the whole of the ordinary shares of the Hammond Company. The Yorkshire, the Birmingham, and the Ferranti Companies will, for the above consideration, transfer to the Hammond Company all their respective undertakings, works, property, rights, and effects, the Hammond Company undertaking to issue and pay all liabilities and the costs of all necessary agreements and of winding-up and dissolving the three companies.

LONDON AND PROVINCIAL ELECTRIC LIGHTING AND POWER (OPERATING) COMPANY.—An order has been made for the compulsory winding-up of this company.

THE STATIST.

EASTERN ELECTRIC LIGHT AND POWER COMPANY.—At the meeting the chairman stated that the sum of £10,000 had already been expended at Hastings under the authority of the Italian Company, and £15,000 had also been spent at Malta, Syracuse, and Genoa. The progress of the company had been very unfortunate. With regard to the future, they hoped to avoid any untoward thing their efforts to be found to carry on the business. If he thought the shareholders would find more money he would ask them to do so on debentures. He was perfectly satisfied that the company could be made to pay, and go on with very large profits. The meeting was going to be done. But that was the difficulty with the shareholders. The chairman replied that was suggestion of the appointment of a committee fell through, and the meeting closed, with a vote of thanks to the chairman.

METROPOLITAN BRUSH ELECTRIC LIGHT AND POWER COMPANY.—At the meeting the chairman said they had decided to put forward with their business and to let how alone. The Hathorn Davey would be a very important, and if it were successful they would proceed with their orders. For the practical carrying out of their work they had entered into an agreement with the Hammond Company. They would not make a call unless they saw their way to employ the money profitably. A shareholder observed that £375,000 had been paid for the concessions, and he believed they would be able to make some use "illegible." The chairman declined to enter into matters of investigation, but repeated that they were should be given to them. It was resolved that the report should be adopted, but that the consideration of the accounts should be postponed "until after the report of a committee of conference."

THE STATIST.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.—The directors have placed the Swan Electric Light Company, Limited, and the Lane-Fox. It has been completed, and in the hands of Mr. St. George Lane-Fox. It has been completed, and in the hands of Mr. St. George Lane-Fox. It has been completed, and in the hands of Mr. St. George

[December 2, 1882.]

THE STATIST.

SUBSIDIARY ELECTRIC COMPANIES.

We elsewhere report the proceedings of the Birmingham and Warwickshire Brush Electric Light and Power Company, and, at considerable length, the explanations of the Earl of Crawford and Balcarres at a meeting of the shareholders of the Brush Electric Light and Power Company of Scotland. In the course of the latter, the Earl referred to the history of the Company in the past, and not the least extraordinary fact in his statement is that applications were sent in for 272,281 shares, of which there were only 20,000 to allot. At the time caused bitter disappointment, but some of those persons who were loudest in their complaints of the smallness of their allotments are now rejoicing for a return of their capital, professing that they were misled by the terms of the prospectus. We understand that those who clamour for the return of their money are very few in number, and their holdings are small, but none the less does their agitation seriously inconvenience the Company, inasmuch as it paralyses its efforts to secure business.

At the meeting, the chairman was careful to point but the glorious uncertainty of the law. The information, as stated in the prospectus, respecting the exclusive rights of the Lane Fox incandescent lamp may be interpreted literally, whether the lamps are sold as "Lane Fox" or as "British." But even were a decision given in favour of those shareholders who ask for their money back, the disposition of the meeting was such that there seems every probability that the main body of the proprietors will continue to work and seek to extend the Brush system of electrical lighting in Scotland. In this policy they accord with the shareholders in other subsidiary Brush Companies who have lately been called together to consider the subject.

Although the progress of electric lighting has not been so rapid as most prophets predicted, there is apparently no reason for the panic recourse of wind-up companies before they have had any chance of obtaining business. It would have been just as reasonable thirty-odd years ago for shareholders in the new English Railways to have pulled up the rails and liquidated their assets, because stock speculators were carried on to an excess. Probably, had it not been for Stock Exchange movements in prices of Electric Companies' shares, we should have had none of the present outcry. We observe that some of the shares of the Companies are quoted in the market actually below the intrinsic value, even if the Companies had been ordered to be wound-up. A liquidation on the worst, should be a matter of a very short time, and inexpensive, if carried out by the officials of the Companies.

[December 30, 1882.]

THE STATIST.

A further decline has taken place in the shares of the Anglo-American Brush and Hammond Electric Light Company. The solicitors of the former Company have advised a contemporary that—"The Corporation never promised an exclusive Lane-Fox licence. No exclusive licence was ever granted by the Corporation, and the Corporation never received a single shilling for granting such licences in England, Scotland, or Ireland." They also state that the Corporation "is in no way accountable for the misstatements in the prospectuses of the sub-Companies."

[March 23, 1882

NATURE

On Wednesday evening, at 9 o'clock, Professor Abel and Rosseo, on behalf of the Chemical Society, the Society of Chemical Industry, and the Institute of Chemistry, received a large number of distinguished guests in the Crystal Palace, where refreshments were provided. Fifteen hundred invitations were issued and accepted, not merely within the limits of the United Kingdom, but in continental countries, and several eminent chemists from France and Germany came over expressly to join the gathering. The Crystal Palace was chosen as the meeting place because of the International Electrical Exhibition now being held there; and the party dispersed themselves about the various exhibits. It was a gala night at the Palace, and the different electric lighting systems were shown at their best. The magnificent display by Edison in the Concert Room and Entertainment Hall elicited much admiration; so also did the fine candelabrum of 96 Maxim lights, executed in cut glass by Messrs. Defries and Sons, and exhibited by the Electric Power and Generator Company. These lights are fed by a Maxim dynamo-electric machine capable of feeding 100 Maxim lamps of 20 candle-power each. The incandescent lamps of Mr. Lane-Fox, exhibited by the Anglo-American Brush Electric Company, the Bright system exhibited by the British Electric Light Company, and the Swan systems were visited in turn, as also were the suite of apartments in the northern gallery lit by Edison's lamps. The visitors scattered about the various stalls, and a special train carried most of them away to town at 9.30 p.m.

[April 28, 188

NATURE

THE *Daily News* New York correspondent telegraphs that the Aldermen have passed, over the mayor's veto, the ordinance giving the Edison Electric Lighting Company permission to lay mains in the streets. "The company will proceed immediately to introduce its new electric lamps in the offices in the business portion of the city around Wall Street. The consumption of the lamp is simple. It consists of a small balloon glass globe, four inches long, an inch and a half in diameter, with a carbon loop which becomes incandescent when the electric current passes through. Each lamp is of sixteen candle-power, with no perceptible variation in intensity. The light is turned on or off with a thumb-screw. Wires have already been put into forty buildings. The company will compete with the gas company, charging the same rates. If the latter reduces, the Edison Company will also reduce, and are prepared to go lower than the gas companies can."

It is known that M. Jamin, member of the French Institute, has patented an electric lamp in which the light is directed hyan electrical current. A public company has been formed with a capital of 8,000,000 francs for the working of the patent.

ELECTRIC LIGHT IN COLLIERIES

AUGUST 9, 1881, witnessed the first practical application in the United Kingdom of the electric light to the illuminating of coal-mines. The Earnock pit, near Hamilton, belonging to Messrs. J. Watson, has been fitted with Swan's incandescent lamps, arranged with water batteries of steel glass, air-tight, and provided with steel guards. The workings in which the lamps were fixed are 118 fathoms, or 708 feet below the surface. Twenty-one brilliant little lights placed at the pit-bottom, in the roads, and at the actual face of the seam where active operations were in progress, supply an illuminator of a very different character from the dismal glimmer of an occasional Davy. The electricity was generated by a dynamo-electric machine at the surface worked by a special 12 horse-power engine, and conveyed by two cables, first along telegraph poles to the pit mouth, then down the shaft to the workings, in one section to a distance of half a mile. The overhead wires are naked copper wires of 3 inch diameter, while those below ground are carefully insulated, and in the shaft are protected with an outer tube of galvanised iron. At suitable points at the circuit safety air-tight switches, the invention of Messrs. Crabtree of Glasgow, are inserted to afford control over individual lamps. The mine was visited two days after the initiation of the light by members of the Mining Institute of Scotland, with whom was Mr. W. Calloway, whose remarkable experiments on the explosive effects of coal-dust will be remembered in connection with the more recent report of Prof. Abel. The party were photographed in the workings. An experiment was made with a lamp to test whether in the event of its being broken by accident a surrounding atmosphere of explosive gas would or would not be kindled by the strip of red-hot carbon before it had had time to cool. Into a box containing about three cubic feet of explosive gas a single lamp, removed from its outer protecting case of iron and glass, was placed, and the current was turned on. The fragile bulb inclosing the incandescent carbon thread was then purposely broken, when the gas inclosed in the box immediately exploded. No such occurrence could possibly happen if the protecting case of stout glass is properly constructed. The risk of accident must be considered an immensely less than that of the ordinary Davy lamp, especially when it is remembered that with the brilliant light of the electric lamps they need no longer be carried in the hand or set down upon the floor near the actual spot where the coal is being got, but will be fixed overhead at a safe distance against the wall of the mine. The easel with which the light can be turned out during the firing of a blast is another point in their favour. The proprietor of the Earnock Colliery is greatly to be congratulated on the step he has taken. In 1880 the death-roll of the shafts by explosions of fire-damp in Great Britain reached the figure of 499 persons. We venture to predict that the universal adoption of electric lighting in fiery mines would reduce this figure to one-tenth of its terrible proportions. How many years will it be, we wonder, before the adoption of electric lighting will be made compulsory by Act of Parliament? And how many colliery owners will discover, we would ask, when driven in this course by compulsion, that in the long run they effect an economy by discarding the clumsy and unsafe "safety"-lamp, which will at once be numbered with the "dint mill" amongst the relics of the past?

AUGUST 12, 1882.

THE METROPOLITAN.

Electric Lighting at Pulham.—At a meeting of the Pulham Board of Works, on Wednesday, a deputation, headed by Mr. Lefevre, the chairman of the West Middlesex Electric Light Company, Limited, waited upon the Board with the object of asking them to grant a wayleave to lay down mains in the streets for the purpose of the company's wires for a space of six months as a trial. The company offered, free of cost, to supply two lamps equal to the light of sixteen gas-burners in the principal part of Broadway and Walton-street for the same period.—Mr. Wright said if the company would undertake to put up a similar lamp in Pulham Fen Town it would influence his vote.—Mr. Lefevre gave the required promise.—In reply to Mr. Sanderson, he said the expense would be borne by the company.—Mr. Stoddard hoped that a light would be thrown on the doings of the Board, as they had been very much in the dark lately. [Laughter.]—In reply to the chairman, Mr. Lefevre said one of the schemes was to supply the Cricketers' Arms with the light.—The Clerk intimated that he had been two similar applications from other companies.—Mr. Stoddard hoped the Board would not entertain the application. He said it was a most shameable thing that the paving and roads should be so frequently disturbed.—Mr. Sanderson would support the scheme. He mentioned that if the cost was double to that of gas, the illuminating power was much greater.—The Clerk here read the West Ham Electric report on the subject, which recommended the Board to sanction the scheme.—Mr. Allen suggested that as it was a highly important question, it should stand over for members to fully consider the matter, and notice could be issued.—Ultimately the application was acceded to, on the company consenting to certain conditions.

South Eastern Electric Light and Power Company.—At a special meeting of the South Eastern (Small) Electric Light and Power Company (Limited), held on Wednesday at the City Terminus Hotel, Cannon Street [Mr. Edward Wright in the chair], a resolution was passed altering the articles of association of the company in certain particulars. The chairman observed that their work up to the present had been of a constant and expanding and organising, for the business which they had no doubt was before them. They applied to the Stock Exchange for the 3rd of June for a settlement, which was granted on the 29th of that month, but they could not obtain a quotation until £5,000 of the capital had been paid up. They had not, however, thought it wise to call up the £1 a share which was due at the end of June, as they had no immediate necessity for utilising the money advantageously. After referring to matters in connection with the organisation and staff of the company, which were working to conclusion, as regarded offices and staff, with the exception of the secretary, he alluded to the successful work which they had at Eastbourne, and to the large installation which they had carried out at Penge Park, and they were also in the Great Eastern Railway yard. They had had numerous applications in reference to installations and the use of electric power, but they had been very busy over the distribution of the mains, and would begin power by day from their mains, and the means of supplying electricity by day and night, and also to a battery or accumulator. Such a system difficulties he believed would now shortly disappear. These matters would be dealt with at once, and formed a control to take into consideration their common interests. The delegates had already met and had established their future mode of procedure. With regard to the Electric Lighting Bill, he expressed his satisfaction at the amendments which were made in the provisional order objected, however, to the compulsory purchase clause.

The Edinburgh Electric Light Company of New York sent out circulars last week to house owners and tenants of their first district, bounded by Spruce, Nassau, and Wall streets and the East River, giving notification that the street conductors are now all laid, and the company is prepared to make the house connections. It is stated by the Vice-President that the lighting of the district will take place by the 1st of September or earlier.—*American Sanitary Engineer.*

On Tuesday night the electric guard at Coventry was illuminated with the electric light, and, at the request of some of the inhabitants, it was decided to utilise it on the following evening for an exhibition football match. The light was equal to 10,000 candles, but the denseness of the shadows added to have rendered it impossible for a great deal of skill to be exhibited.

After a time they die. Their ill-health under these circumstances is apparently due not merely to the want of food, since they die sufficient trouble the small Entomostraca on which they feed can be supplied to them, but to the very fact of confinement in a small receptacle. They require a large bulk of water. Flavitatile organisms can be kept in a small vessel by means of a constant stream poured through the vessel, and organisms which inhabit small pools present no difficulty. But insertive forms are very difficult to deal with. Should the Medusæ reappear this year, it is my intention (with the permission of the authorities) to partially submerge a vessel with freely perforated sides in the large tank, the bottom of such vessel to be imperforate, and the vessel itself two feet in diameter and three feet in depth. If a sufficient number of the first brood of young Medusæ can be cultivated in this vessel through the summer, both males and females (unless the females have some altogether unsuspected history) will in all probability arrive at maturity, and reproduce in it as they clearly enough have done in the Regent's Park tank between 1880 and 1881. It will then be possible from time to time to examine carefully the contents of this experimental vessel. I need not say that I should be very glad if others would carry out a similar experiment.

E. RAY LANKESTER

ELECTRICITY AT THE CRYSTAL PALACE

II.—*Edison's Electric Light*

THE centre of interest as the exhibition of electricity in the Crystal Palace, formally opened on Saturday by the Duke and Duchess of Edinburgh, will unquestionably be the show of Mr. Edison. His electric light in the Entertainment Court and the Concert Room is by far the finest ever yet made, and is of itself a spectacle to be remembered. No expense has been spared to demonstrate the power and beauty of his incandescent lamps, and the divisibility of the current to meet the needs of domestic lighting while Messrs. Verity and Sons have seized the occasion to illustrate their skill to show how eminently adapted the electric light is for ornamental purposes. The heated filament of carbon inclosed in a vacuous bulb of glass is well fitted for all kinds of domestic illumination by reason of its pure and absolutely steady glow, its healthiness and freedom from noxious fumes, and its comparative coolness. But in addition to its superiority over gas, oil, and candles in these respects, the Edison exhibit also proves in the most striking manner its superiority as a decorative light, and its unrivalled capacities for enhancing the artistic pleasures of our homes. Realising giving off an cute colours, the incandescent lamp lends itself to the designer's fancies in a way which no other illuminant can; and we may expect something like a revolution in household decoration by its introduction, as well as a new development of the brass-worker and the glass-blower's art.

Before considering the apparatus employed by Mr. Edison at the Crystal Palace for the production and distribution of the light, we shall briefly describe the results, readily a small cluster, the principal object of interest is a magnificent chandelier suspended from the middle of the ceiling. This beautiful object is in itself a work of art, and sustains ninety-nine incandescent lamps. It is ceiling. This beautiful object is in itself a work of art, and sustains ninety-nine incandescent lamps. It is constant feet in diameter at the lower end; while its weight is half a ton. In device it represents a tapering bouquet of flowers springing out of a golden basket. The stem of each flower springs from a circular brass plate within the basket, and bends over towards the spectator, presenting its calyx of coloured glass, in which is fixed an incandescent lamp. The foliage is all of hammered brass, richly gilt, and here and there is mingled with the sun-flower or tiger-lily, and some rambling sprays of fern. The corolla of the flowers containing the lamps, and acting as their shades, are in the form of tulips and hyacinths, made of glass, and tinted with a variety of colours—pearl, white, ruby, clear olive, and clouded blue. Each lamp projects from the heart of the flower like an enlarged pistil, and throws its light outwards and downwards into the room below. The lights are controlled in three sections by turncocks, like gas, and thus a graduated effect can be obtained, or all the lights may be put on or off at will.

On each side of the stage, which is furnished with a row of twenty-four footlights, there is a pretty candelabra[1] mounted on a short marble column, and representing a vase-bush springing from a golden urn. The stem of the bush is entwined with China roses, and crowned with five upright lamps or candles, like the fruit of the tree. On the left of the stage is hung an exquisite little chandelier or lustre of Venetian glass, which, though far less imposing than its gaudier neighbour in the centre of the hall, is chaster and more elegant, and better fitted for an ordinary drawing-room. It is about four feet high, and consists of loops and festoons of crystal drops on gilded chains, encircled at the bottom by a ring of fourteen lamps; and inclosing higher up a single incandescent bulb of ruby glass under a bell shade of the same material. The use of coloured glass for the vacuous bulb itself is illustrated here, and shows how the light can be tinted to harmonise with any interior furnishing, or suit the taste and eyesight of individuals. The influence of the glowing carbon in a transparent bulb is not too strong for the ordinary eye to look at with impunity; but the presence of weak sight may have it reduced by the use of clouded bulbs, and students, or those suffering from diseases of the eye can employ bulbs of green or blue glass. Photographers, too, can have recourse to ruby lamps in the development of their negatives.

On the right side of the stage there is a third chandelier of gilt brass, with twelve naked bulbs, a number of single lamps on stands or movable brackets, like gas-jets, with turn-cocks, and either naked or shaded by flat conical reflectors of opal glass. Specimens of these are shown in Figs. 1 and 2. Then there are ball-lanterns of brass, inclosing clusters of bulbs, window-lights, a very handsome billiard lamp, containing six set of twin lamps, shaded from the eyes of the players by opal glass reflectors and crimson fringes, and two handsome drawing-room shade-lamps of the same pattern, each containing a cluster of eight bulbs inside, and one lamp supplemented by four pairs of naked bulbs outside. Bulbs are also shown burning under water, either clear or tinted, to illustrate the use of the incandescent system in fire mines, and there is a specimen of a regulator lamp by which the power of the jet can be graduated at will like a gas-flame, by simply turning the cock. This lamp is shown in Fig. 3, the lower being the regulating socket by inserting the resistance of a series of vertical carbon rods into the circuit. This is done by turning the screw-piece at the base of the cylinder inclosing the circuits and keep them cool.

In the top of the lamp the novelty is the form of the contact surfaces to prevent sparking or breaking the circuit. These are conical, the small cone seen on the top of the figure being forced away from a conical cup on turning the screw plug. The large surfaces of the cones prevent simultaneously separating, and prevent a large spark. A safe-guard for the lamp against a too powerful current is provided in a short fusal wire, seen running from the left of the figure. When the current is too strong this wire fuses, and the current of the lamp is interrupted.

[1] Electroliers and electrosliers would be the corresponding terms.

In addition to these lamps Mr. Edison also exhibits some very handsome sconce mirrors supplied by Messrs. Verity and Sons. One of these is a novelty in its way, since the bulb lighting it is inside the frame, and therefore

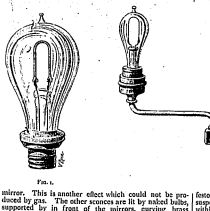

FIG. 1.

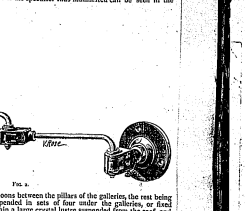

FIG. 2.

mirror. This is another effect which could not be produced by gas. The other sconces are lit by naked bulbs, supported by in front of the mirrors, curving brass brackets in which the rolling idea of foliage and flower or fruit is elegantly worked out.

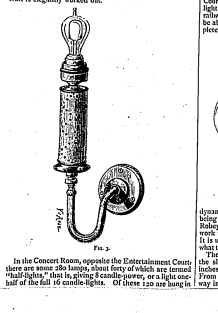

FIG. 3.

In the Concert Room, opposite the Entertainment Court there are some 280 lamps, about forty of which are termed "half-lights," that is, giving 8 candle-power, or a light one-half of the full 16 candle-lights. Of these 120 are hung in festoons between the pillars of the galleries, the rest being suspended in sets of four under the galleries, or fixed within a large crystal lustre suspended from the roof, and looking like a nest of diamonds. In the Entertainment Court and Concert Room together there are nearly 600 lights, and the same number in the side avenue leading to the railway station, have yet to be lighted. In all there will be about 700 lamps required when the exhibit is complete. To drive the 500 lamps now going there are eight

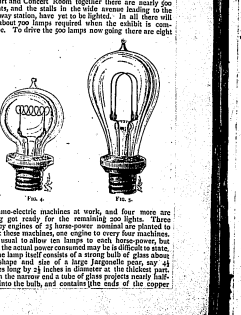

FIG. 4.

dynamo-electric machines at work, and four more are being got ready for the remaining 200 lights. Three Rabbeth engines of 25 horse-power nominal are planted to work these machines, one engine to every four machines. It is usual to allow ten lamps to each horse-power, but what the actual power consumed may be is difficult to state.

The lamp itself consists of a strong bulb of glass about the shape and size of a large Jargonelle pear, say 4½ inches long by 3½ inches in diameter at the thickest part. From the narrow end a tube of glass projects nearly half-way into the bulb, and contains the ends of the copper

conducting wires or electrodes. The inner end of this tube is closed by a flat keel of solid glass, but the wires pass through this into the upper part of the bulb, where they are connected by an electrotype of copper to a fine loop or arch of carbonised woody fibre cut from the siliceous skin of the bamboo cane. Mr. Edison exhibits specimens of bamboo from China, Japan, and South America, as well as fibres from Brazil, which he has tested in seeking a good and durable carbon for his lamps. He shows also a number of samples of the carbonised loops made by simple charring in a crucible or by treatment after the Sherbolier process, as well as loops of pure graphitic very carefully cut. What the particular bamboo is that he has finally adopted we have never been able to learn, but it is probably a variety of the "Shikishashikee" of Japan, which yield a very close and even skin. The carbon loop is about ¾ inches high, and 1 inch wide, and is so fine that its electric resistance is about 100 ohms, in the "16-candle lamps," and about 50 ohms, in the 8-candle lamps. All the lamps at the Crystal Palace are plain single loop lamps; but sometimes Mr. Edison combines two or more loops, as shown in Figs. 4 and 5. These loops can either be coupled up "in series," or "quantity," and

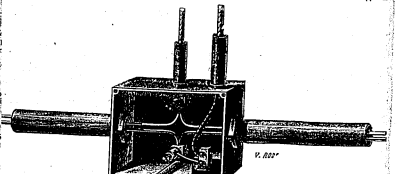

FIG. 6.

cross-section, like a segment of a circle. Two of these, the outgoing and return wire, are inclosed a little again in the same iron pipe and insulated by a black compound resembling Thomson's vax. Branch-conductors in the form of cables for side-streets are connected to the mains in a joint-box shown in Fig. 6. This consists of an iron box in which the mains are connected to two iron terminals. One branch cable is connected to one of these terminals direct, and the other through a short piece of lead to the other terminal. The lead acts as a fuse-wire in fusing if the current is too powerful. The box is hermetically sealed, to keep the inside dry. The conductors led into the houses are of a still smaller size, having a diameter of from two to three millimetres; but throughout the whole system the going and returning wires keep together, and the lamps are simply connected across between them. In each lamp, too, there is a similar safety connection of lead to protect the carbon if the current is too strong.

The incandescent system has evidently been brought to great perfection by Mr. Edison, backed as he is by plenty of capital and skilled assistance. Although the idea of it is not new, and was patented in England by Mr. Starr in 1845, Mr. Edison deserves great credit for working it out in so practical a form. Starr described a vacuous bulb of glass containing a thin rod of carbon rendered incandescent by the passage of the current, and Mr. Edison found in this the rough pebble which he has cut and polished with so much success. Moreover, he saw the merits of the incandescent system for domestic lighting at a time when other electricians were giving all their attention to the arc light; and therein showed his genius and foresight. For it is evident now to electricians that while the arc light is well enough adapted for the lighting of large areas, it is unsuitable for small interiors. The practical success of Mr. Edison's system is not thus for a complete justification of his early promises, for the cost is still an unknown quantity, as far as the public are concerned, and there are strong reasons for believing that it will not nearly be so low as the startling figure held out in 1878.

instead of making the loops plain they may be coiled into a spiral form. The air being exhausted from the bulb, there is no oxidation of the carbon after a short time and Mr. Edison claims that his lamps will last 1000 hours. This at an average rate of between three and four lighting hours per night would give a life of nine months to each lamp; but the estimate may be found a little partial in practice; for though the carbon does not burn, it is doubtless slowly dissipated by the wasting action of the gases and the energy of the current. As Mr. Edison claims to make the lamps at a shilling each, their durability is not so very important as it might at first appear. The Edison dynamo electric machine consists of two vertical electromagnets inclosing between their lower pole pieces of soft iron, a revolving armature. In the armature the usual coils of insulated wire are replaced by longitudinal bars of copper of trapezoidal section insulated from each other by brown paper. These bars are connected to the slips of the commutator in such a manner as to give a continuous circuit through the bars and a continuous current to the brushes when the armature revolves. The main conductor conveying the current from the machine consists of a solid rod of copper in

NOTES

At the annual meeting of the Geological Society the medals were presented as follows:—The Wollaston Gold Medal to Dr. Franz Ritter von Hauer, Director of the Austrian Geological Survey; the Murchison Medal to Prof. Jules Gosselet, of Lille;

ELECTRIC LIGHTING

I.

ONE of the greatest experiments ever made in street illumination by means of the electric light was commenced on Monday night in the City of London. The extensive area of the City authorities in this direction is the more commendable, inasmuch as they had previously tried electric lighting on the Holborn Viaduct and in Billingsgate Market with very poor success. In fact, in those two instances the experiment was a decided failure.

Now however, gaining experience from the advances that have been made in other directions, and especially from the great success attending the illumination of several railway stations, the City authorities have resolved to divide the City into three districts for the purpose of experiment.

1. The London Bridge district; embracing London Bridge, Adelaide Place, King William Street, the front of the Royal Exchange and Mansion House, the Poultry, a part of Cheapside as far as King Street, the upper part of Queen Street, King Street, and the Guildhall Yard.

2. The Blackfriars Bridge district; embracing Blackfriars Bridge, New Bridge Street, Ludgate Circus, Ludgate Hill, St. Paul's Churchyard (south side), and the remaining portion of Cheapside beyond King Street.

3. The third district has not been lit up, and therefore need not refer to it.

The first district is being lit up by Messrs. Siemens Brothers at a total cost of 2735*l.* for the twelve months, replacing 138 gas-lamps. The other district has been lit up by the Anglo-American Electric Light Company, on the Brush system, for a total cost of 1100*l.*, replacing 150 gas-lamps.

Before drawing any comparison between these two systems it will be just as well to describe how each has been carried out.

The Messrs. Siemens have applied to their (No. 1) district six powerful lights, fixed at a height of 80 feet from the street level upon tall latticed iron masts similar to those which are used on many railways for signalling purposes. They have also twenty-eight smaller lights, carried upon special iron posts, considerably higher than the ordinary lamp-posts, being 40 feet from the pavement. The powerful lights, fixed high up in air, are used more for the illumination of open spaces, and this system—a special feature of Dr. Siemens'—has been very extensively adopted at the Albert Docks, Blackpool, and other places. The central station of the Siemens system is in Old Swan Lane. Here three engines, supplied by Messrs. Marshall of Gainsborough, of their semi-portable type, and of 10-horse power each, fixed with an admirable automatic expansion gear (Harrnell's) specially applicable to engines used for electric lighting purposes, are fixed. Two of these engines are always at work during the time of lighting, but one is kept in reserve, ready at a moment's notice to replace either that may fail. These engines, by means of bevings and a counter-shaft, apply their power to various dynamo-machines of the well-known Siemens type. Each of the high lights is worked by a separate and distinct dynamo-machine, with which it is connected by separate conducting-wires. The wires throughout the whole of the City are of thick copper, very well insulated, and laid under ground in the customary manner of laying down wires for telegraphic purposes. The smaller lights are worked by alternating currents on the system with which we are familiar on the Thames Embankment applied to the Jablochkoff candles. In Swan Lane there are two of seven lights each, the lamps being arranged so that consecutive lamps are on the same circuit, and by that means, if any accident should occur to one set of lamps it would only extinguish one out of two lights in a street, and not throw the whole district into darkness, which would be the case if all the lights were worked on one circuit. The field-magnets in all the large dynamo-machines are excited by a similar dynamo-machine, while the magnets of the alternating current machines are fed by currents from a smaller continuous dynamo-machine. Each large machine absorbs between 4- and 5-horse power, but the alternating machines require much less. The furthest light from the generating centre—Old Swan Lane—is that in front of the Guildhall, which is nearly three quarters of a mile distant, involving a length of wire of 7200 yards (a return wire being used), whose total resistance does not exceed one Siemens' unit. The illuminating power of the high lights is estimated to be 6000 candles, but it is well known that this estimate of the illuminating power of an electric light is a very wild one. There is no doubt that the lights are very powerful, and a stream of brilliant illumination is thrown all over such an area as that in front of the Royal Exchange. The Siemens' lamps burn for eighteen consecutive hours, owing to the size and length of the carbons used. They are provided with reflectors which throw a bright cone of light down in a very effective way, giving to this experiment a very marked feature.

There is no doubt whatever that when it is required to illuminate a large area this is very much more efficiently and economically done by using one single powerful light high up in air, than by distributing several smaller lights over the surface. In the former case the light is more evenly, uniformly, and perfectly diffused, in fact it acquires the character of bright moonlight, while in the latter case the light is distributed in patches of intensity and darkness over the whole space.

When streets are dealt with the conditions are different, and it is here quite easy to show that economy and efficiency are provided for by properly distributing smaller lights along the street. The Messrs. Siemens have set to work to solve this problem in a scientific way, and Mr. Alexander Siemens, under whose control and management the system has been carried out, can show mathematically that to distribute light uniformly and properly a certain definite proportion should exist between the height of the posts and the distance at which they are apart. That this has been carried out is abundantly evident by the very even way in which light is distributed along Queen Street, King William Street, and Cheapside. Indeed it is difficult to see any break in the intensity of the light along the route—a proof that the practical application of the law very nearly approaches its theoretical limit. The theoretical point to be aimed at is that the height of the poles should be to half the distance between them as 1 is to the square root of 2. This has not been absolutely obtained, but a very close approach to it. The small lights only give an illuminating power, according to Messrs. Siemens, of 300 candles, and this probably is well within the mark. Comparisons between lights of low intensity are very easily and accurately measured; it is with when a power of many thousand candles is arrived at that the failure of comparison with a standard candle becomes evident.

The high lights have not been burning uniformly with that steadiness that success demands. Failures sometimes are not numerous, though they have been frequent. The smaller lights, on the other hand, have worked more uniformly, and have given considerable satisfaction. The strong shadows thrown by the high lights have a very weird-like effect in certain positions, and the vibration of the lamps gives to the shadows a life-like appearance at an unsteadiness that has led the unwary to imagine in many instances it at the pole itself was shaking. Could the shadows be removed from the effects of these high lights the effect would be very fine; as it is they detract enormously from the beauty of the lamps. The effect of the high lights in those standing below is excessively glaring, and doubtless in warmer weather will be more highly appreciated than it has been during the past week. It is when crossing streets, and especially when crossing Mansion House that these lights show their efficiency to advantage. It is quite amusing to see how the *gamins* of London have taken advantage of the combination of electric lighting and asphalte road to convert the whole City into a gigantic skating-rink. Hundreds of boys are to be seen every night disporting themselves on their roller-skates.

we breakfasted with them in one of the most picturesque nooks imaginable, and finally how we realised with difficulty that we were only three days' journey from London while breakfasting, under a bower of cacutha branches, off sheep roasted whole over hot ashes and basted to baks in the earth, manipulated with hunting-knives and wished forks, flat circular cakes of Indian bread serving as for plates, and gigantic wooden bowls of *kous-kous* as a second course.

The amicable attitude of these once savage aborigines seemed to us to re-echo the key-note of the Algiers meeting of the French Association; to proclaim loudly and with no uncertain sound that the "conquête pacifique de l'Afrique septentrionale par les Français" has indeed become an accomplished fact.

G. F. RODWELL

ELECTRIC LIGHTING

II.

THE second district of the City which has been illuminated by electricity is that embracing Blackfriars Bridge, upon which there are seven lamps; Bridge taking three lamps; Ludgate Hill four lamps; Ludgate Circus and St. Paul's six lamps; and Cheapside, as far as King Street, eight lamps; thirty-two lamps in all, replacing 130 gas-lamps; and moreover, all these lamps are fixed upon one circuit, which is operated practically by only one machine, and that lived more than a mile away, at the manufactory of the Brush Company in York Road, Lambeth. The total length of this circuit is over 20,000 feet. It consists of a copper cable made up of seven best copper wires successfully secured, and they are about to replace their conductor by a better one. They will have to pay dearly for their neglect of common experience.

So far the experiment has shown that the practical lighting of streets by electricity is not only feasible but practicable. Moonlight has certainly been thrown into the shade, for the streams of light are better illuminated by electricity than by fair Luna. It is quite possible to read a letter or to see one's watch at any point in King William Street. Indeed the smallest object can be seen anywhere on the whole length of the road. Running-over has been rendered impossible.

In the outside districts not specially favoured are clamouring for electric lighting, but much has yet to be learnt before the system can be determined as final. For instance, we have the Lontin system to be tried, and we should certainly like to see that most energetic and successful engineer, Mr. Crompton, test his system in the London streets. Incandescent lamps are looking up and deserve a trial.

The Brush system of lighting has not yet been settled.

It would seem that a compromise between the centre-fixed system of Siemens and the distributed system of the Brush Company will have to be resorted to before the problem of proper street illumination. But instead of carrying lamps irregularly down streets on ribbons lamp-posts it would almost seem that the ancient street mode of suspending lamps across streets from housetops would be a better mode of illuminating streets. Take, for instance, Cheapside. If that street had suspended above it, at the height of 40 feet or 50 feet and at about every 100 yards, a Brush lamp fixed on the top of a graceful iron arch, or suspended on wire ropes between the tops of the houses, nothing could possibly be greater than the effect. Light shadows thrown across the street might even be a convenient mode of suspending the wires forming the circuits, for overhead wires have a considerable advantage over underground wires in this, that they cool more readily than wires that are surrounded by gases to pass through. More than that, they require no insulation, and the money thrown into their insulation could be thrown

† Continued from p. 9.

ELECTRIC LIGHTING MEMORANDA.

THE hitch in the boasted progress of electric lighting, which consists in the fact that the householder—or, for that matter, the householder anywhere—is apparently as far as ever from any possibility of obtaining a supply, has been the occasion of some more writing in the columns of *The Times*. A gentleman living in South Kensington complains that having just built a couple of new houses, for himself and a friend, which he has had "wired" for electric lighting, there is as yet no prospect of having the wires utilized. The editorial article of *The Times* have given heed to this matter, and have published which, for its lumpy assurance of knowing all about it, and blaming everybody all round might be mentioned to the illustrious head of the Home Office. The writer shrewdly suggests that the reason Electric Lighting Companies have not done more in the way of private trade, is because most of them are wrongly constituted, and the rests are not ready to house

ELECTRIC LIGHTING MEMORANDA.

The last electric lighting venture which has drawn down the damnations of the Editor of *Money* is the London and Provincial Electric Lighting and Power Generating Company —a concern ecstatically puffed in these columns as enjoying the right to use the Gramme dynamo, the Jrrisford incandescent lamp, and the Chertsprue arc lamp. For these rights and privileges the Directors of the fledgling Company engaged to pay the vendors the modest sum of £70,000; of which £10,000 was to be in shares and £60,000 in cash. The market was becoming glutted when the subscription for this valuable property was opened; and therefore the public contributions amounted only barely to the amount due to the vendors. The Company were thus left without any working capital at all. Notwithstanding this unpleasant circumstance, the Directors proceeded to allotment—a transaction which is stigmatized by our financial contemporary as a gross contravention of the spirit of the Companies' Acts. Under these conditions, the utmost the Board could do was to defer the payment of a portion of the purchase-money, amounting in all to £12,000; otherwise no business whatever could possibly have been done. As it is, the machinery, plant, and office furniture belonging to the undertaking are valued at only £2650—and this is all whereby patents valued at £70,000 are to put in operation! On the past year's working there has been an admitted loss of nearly £1000; though the particulars of the amount are not published. It is suggested that probably the greater part of the money has been liberally squandered in Directors' fees, and so forth; yet the Board are anxious to impress upon the proprietors that their fees are still in abeyance to the extent of £900. Unless the shareholders are unusually generous, this sum will hardly be realized at present; for the faces of working the concern cannot be played much longer.

Really, the simplicamus of *Tat* goes towards the speculative electricians is most persistent. Last week the Editor remarked the notorious Mr. Robert Hammond to occupy the letter part of a column with a letter vaunting the advantages of electric lighting, and purporting to make the position of the system "quite clear." The only line that is at all clear about it, however, is that Mr. Hammond means to show the shareholders who pay his salary that he can earn it as well by letter-writing as by lecturing. Of course, Mr. Hammond does not write to "advocate any particular system," or to "extol any particular patentee," but to give a friendly lift all round. His history is incomplete, for he does not explain how it is that all the Electric Lighting Companies have lost so much of their money. Yet no man knows more about the lighting question. His allusions to the future are also very unsatisfactory, for he promises "during the coming twelve months a period of probation, which it is it is to be hoped will be the last" before the question of electric light distribution on a large scale is completely set at rest. A good many other things will be "set at rest" before this point is reached; the majority of the present order of Electric Lighting Companies and their promoters being among the number.

The authorities of the quiet town of Colchester are greatly troubled respecting their pavements. It appears that they have entered into engagements with one of the Brush Electric Lighting Companies for an installation, which is described by a local newspaper as the most complete and advanced lighting undertaking in the whole world. The first result of the Company's operations, however, has been to disorder the principal thoroughfares in the most reckless manner; for the cables intended to be placed therein are ready, and some streets have been dug up twice when, by the exercise of a little common foresight, once would have sufficed. Even for, as usual with this class of Companies, excuses and pro-

ELECTRIC LIGHTING MEMORANDA.

Of all modern Electric Lighting Companies formed for the purpose of carrying on business in London, the most respectable, in a business sense, has been the Jablochkoff. While the others have been all talk and no public lighting, this Company has been carrying out contracts under the Metropolitan Board of Works, and for several pieces of business in different parts of London. It is the oldest of the modern lot; and it might be supposed that, if there is any profit in the lozinges to which it is devoted, this concern would have found it by the present time. Yet, from the Directors' report and statement of accounts just issued, the Company appears to be in precisely the same case as their rivals. When the Jablochkoff promoters sold the business to the present Company, the price paid was £165,469, for which they obtained a patent licence, a wooden shed on the Thames Embankment (containing a 30-horse portable engine and dynamos), and a contract to light the Embankment at a heavy annual loss. Besides all this, they had "hopes" of doing a large and increasing trade all over the country. Those hopes have not been realized, and the past year's operations have resulted in a loss of £14,499, which is called a "suspense account"—probably because it is unwilling to be written off as a dead loss. Of this sum no less than £7776 is in Directors' fees, salary, and "sundries;" which shows how difficult it is to conduct such a business, and how so much money in it, in so short a time. Directors and staff must indeed have worked hard. Our contemporary *Money* is very wrathful in its comments on these accounts, which are qualified as patently showing the concern to be on its last legs. It certainly does not look well for the prospects of the "Jablochkoff" system of lighting in England. It will soon become a question as to how to be done with the Thames Embankment experiment. Will the Board of Works carry it on at a cost of something between £600 and £700 a year above the contract price?

The principal topic of interest in connection with electric lighting is the amalgamation of the Swan and Edison interests in this country. This was effected at two extraordinary general meetings on Monday and Tuesday last week, when the proposal was sanctioned by the proprietors of both Companies. The financial arrangements are of a complicated character, and not to be easily explained in the space at our command. It appears that up to the present time, on business in Great Britain alone, the Swan Company have spent £188,917, and the Edison Company have laid out £100,000. It was, of course, unnecessary for the purpose in view to show how these amounts were made up. The Edison Company will receive the Swan Company in respect of an obligation to pay to Mr. Edison half of their profits over 6 per cent.; and this obligation Mr. Edison has decided to abandon. Consequently, he will receive the proportion of deferred shares in the United Company. The capital expenditure of both Companies will be represented by shares, a proportion of which will be issued as partly paid, in the United Company. All the Directors regard the arrangement as "wise, reasonable, and just" to all parties; and so everybody is happy.

The usual course and consequence of experimental electric lighting has been very conspicuously followed in the case of Pentonville Road, which the Maxim-Weston Company contracted to light for the Vestry of Clerkenwell. At first high descent lamps were used, but proved miserably ineffective, and are lamps were substituted. It has been known for some time that the Company did not intend to renew their tender, and wished to sell their plant to the Vestry at about half price. Meanwhile, however, the main conducting cable broke down, and the lighting came to a premature end on the 27th ult. Under these circumstances, the Lighting Committee of the Vestry formed the natural conclusion that the electrical plant would be dear at any price; and the use of gas was forthwith resumed. The brilliant electric lamps, however, had left in the minds of the Committee the usual craving for better light; and they have decided not to return to their old 6-feet gas-burners, but to indulge in better lanterns and burners consuming 16 cubic feet of gas per hour. The proposal has not yet been adopted by the Vestry; but its existence is a sufficient indication of the good that comes to gas from electricity. The additional revenue to the Gas Company for the thoroughfare in question, under this arrangement, would be £2230 per annum. Some discontent at the prospect of the increased outlay is being expressed by ratepayers of richer and less favoured parts of the parish; but it has been learnt by the majority, at the cost of the unfortunate Maxim-Weston Company, that if streets are to be well and reliably lighted it must be done by gas.

Considerable jubilation has been expressed in certain of the electrical journals over improvements recently effected by Dr. Hopkinson in the Edison dynamo. Everybody knows that the Edison dynamo was always the best machine of its class in the market; but we at first were somewhat startled to learn that Dr. Hopkinson had succeeded in increasing threefold the efficiency of the dynamo. Having re-designed the machine, Dr. Hopkinson has managed to strengthen the magnetic field; and now a machine which was formerly employed for 60 lamps will keep up 200 lamps of equal brilliancy and power. Results are, however, it is made apparent that this wonderful improvement is a small matter after all, for the motive power to perform the high duty must be correspondingly increased, just as though three machines were used instead of one. Moreover, it is admitted that the electrical efficiency of the improved machine is a trifle lower than the results given by some other Edison dynamos of the same size.

The principal advantage derivable from the new pattern is, therefore, a slight saving in friction due to working one machine instead of three. As it is to be understood that the Hopkinson modification forms the basis of at least one more patent, it is difficult to see that these improvements, however theoretically interesting, can have the slightest beneficial influence upon the practical development of Edison lighting.

Metropolitan (London), Jan. 1883.

Mr J. W. Swan, inventor of the well-known electric incandescent lamp bearing his name, is about to leave Newcastle and take up his residence in London, with the view of directing the operations of the company.

At a meeting of the Fulham Vestry Committee on Wednesday, it was stated that the South-Eastern ("Brush") Electric Light Company was the only one that had made an application to supply the electric light to the town. Under one section the Company take powers to supply light as soon as it is known as the "Brush" system, for which the charge will be £4 10s. for the first 100 lights "and 30s. per" unit "afterwards." By a "unit" the Town Clerk explained, was meant sufficient energy to light a 20-candle-power lamp for 1½ hours. One of the members said this charge would be found to be exorbitant.

A novel application of the electrical transmission of power has lately been made at the Trafalgar Collieries, Forest of Dean, where an electric motor is employed to drive a pump in the underground workings. A dynamo machine is placed on the surface for generating the current for working the motor, and is connected to it by wires laid down the shaft and along the workings, a distance of some 500 yards.

On the 29th ult., the Mayor and Corporation of Leicester and the leading manufacturers attended at the hosiery manufactory of Messrs. Corah, Sons, and Cooper, Leicester, to witness the first introduction of the electric light into a textile factory in the town. The Brush and Swan incandescent systems are both used.

ELECTRIC LIGHTING MEMORANDA.

The latest of the deputations that have troubled Mr. Chamberlain in regard to the working of the Electric Lighting Act was one of electricians, or rather of would-be speculators in Electric Lighting Companies. The deputation complained bitterly of the determination taken by the Board of Trade to make sure of the financial position of licensed undertakers of electric lighting, by ordering the deposit with the local authority of the district in question of one-half of the necessary capital for every such installation. It was alleged that the effect of this stringent regulation would be to cause the abandonment of many schemes of this class. In reply, Mr. Chamberlain hinted that such a communication was unlikely to be wished in many instances where bogus companies sought to acquire powers which, if granted upon the terms asked, would have placed whole districts in the hands of people who had no knowledge, no ability, and no means, and who were simply "speculators with other people's money." Incidentally, Mr. Chamberlain made a remark that will be regarded by many people as amounting, under the circumstances, to a good joke. He said he did not care to undertake the appointment of the inspectors of the working of electric lighting establishments, because "he did not like the idea of centralization, of which they had already too much." From this it might be inferred that the President of the Board of Trade, having in the present session made proposals for taking possession of the Patent Office and bankruptcy affairs, in addition to the already numerous establishments of his peculiarly centralized department, will initiate no more propositions of the kind during the lifetime of this Administration.

It has been reported that the great fire at the Parliament Houses in October was caused by the electric light, or the fittings in connection with the same. Mr. Spencer Smith, therefore, has written to the *National Zeitung* admitting the possibility of this cause, and suggesting that electric lighting companies is capable of producing fire, unless protected with the greatest care and knowledge. He goes on to say: "Some of this kind of lighting, which are without the necessary knowledge and experience; and, in their efforts to make electric lighting as cheap as possible, are overstepping the limits of safety. This observation is in strong confirmation of Mr. Chamberlain's remarks mentioned above; and it will strengthen the precautionary measures insisted upon by the Government to make sure that unexperienced electricians shall at least have the means of paying for any damage they may cause. Indemnity to the same purport is also unwillingly borne by a company to the same purport is also unwillingly borne by a company to the same purport is also unwillingly borne by a company

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT. [Jan. 6, 1880.]

ELECTRIC LIGHTING MEMORANDA.

The prospects of electric lighting are discussed in a recent issue of the *Electrical Review*, in an article which begins by asking whether any real advance has been made in this regard since the close of 1882. It is considered that the gloomy period through which electric lighting companies are now passing gives more hope for the future than did the circumstances of the era of wild electrical speculation. This is undoubtedly true in one respect—it confines inventors to the "fathers of invention," and excludes the latter class, present. It is confessed that the number of solvent electric lighting companies remaining may be counted on the fingers of one hand; and that the only remunerative business for them appears to be in fitting up steamboats with incandescent lamps. As far as the great question of house-to-house lighting is concerned, our contemporary admits that there does not appear to have been the least advance. "We can still only point to the admirable installation of the Edison Company on the Holborn Viaduct, which, however, has not been augmented by any additional circuits." The spasmodic attempts to force upon the public attention electric lighting by means of primary batteries, are mentioned only to be condemned. The possible utility of primary batteries is admitted; "but they should not be brought forward as a "cheap means of producing electrical energy." On the other hand, it is admitted that "accumulators have turned out "decidedly disappointing." On the whole, however, the *Electrical Review* holds that such electric lighting as is done in the immediate future will be better done; speculation will give place to steady business; and "electric lighting will "eventually assume a position which, although it may never "equal that of gas, will at least be one of considerable "importance amongst the industries of our country." In this aspiration it may be hoped that our contemporary will not experience further disappointment.

Notice of application for prolongation of patent has been given on behalf of the inventors of the Gramme dynamo, where rights would otherwise expire in regular course on 26th of June next. The patent is now vested in the British Electric Light Company. It is understood that, if the monopoly should not be prolonged in this instance, the trade in dynamos will go to pieces; for the Gramme machine is equal to any other in the market, and whoever controls this system will practically rule the land and fix the prices for the remainder. When Gramme machines are made and sold in the open market for the ordinary trade profit, it is scarcely likely that users will give four or five times as much money for some new patented machines of merely imaginary superiority. No open market for the ordinary trade profit, it is scarcely for some new patented machines of merely imaginary superiority. There are sufficient electrical engineers to design new dynamos, and D'Arsonval will be able to satisfy the Judicial Committee of the Privy Council that they have not yet received sufficient compensation for their invention.

Mr. Oscar Offner, now styled Manager of the Consolidated Electric Company—which is the name assumed by the group of lime Brush Companies who are now trying to prop one another up—has been lecturing at Dudley, under the auspices of the Mayor and Corporation. Dudley is said to be one of the towns for which the South Staffordshire Electric Light Company have obtained a Provisional Order. This possibly accounts for Mr. Offner's presence, probably as a substitute for Mr. Hammond. The intended lectures will be wondering how, if his Company should hold his wondering they would put down generating plant in the centre of the town; and "their next course would be to place in different "parts of the town a storage of electricity . . . so that "if the machine broke down they would still have a constant "supply of electricity which was stored up just in the same "way that gas was stored in the gasholders." We have no particular desire to visit Dudley; but we should start off by the next train if we could believe that the well-known Brush lamps, which the old original Company cannot keep constantly going in London, were being marked there as Mr. pleasure, as there is usually a long interval between the appearance of the electrical lecturer and the establishment of the lighting station. And even if the Consolidated group of failures should keep afloat long enough to make a businesslike "course"—of the electrical gasbaldders—would appear might the people of Dudley was a deliberate hoax. He must have been done elsewhere, and that there was no reasonable prospect of it for Dudley. And as for his boast that his Company "could pay their way, and not charge customers more than they were now paying for gas"—where is the Brush Company able to "pay their way," to say nothing about the latter condition?

Mitchell's Gas (London) July 15th.

The directors of the Great Western Electric Light and Power Company (Limited) announce that the Swedish and Cornwall Electric Light and Power Company (Limited) have ratified the arrangements with the Company for paying the £11,000 for the subscribers and concessions as agreed.

The Stratford Electric Lighting, Power, and Regulator Company, Limited, announces that the shares offered to the public not having been fully subscribed, the deposits paid on application will further be returned at once without deduction. The company's offices have been ordered from New York, a full installation of their system will be shortly made.

The South Electric Light Co. of Ireland was registered on the 30th ult., with a capital of £250,000, to acquire a concession from the Anglo-American Brush Electric Light Corporation.

The electric light is being introduced in the town of Cirencester, near Cirencester. There are to be five large arc lights, four of these being along the cliff which overlooks the sea, and forty-two small incandescent lamps of the Latte-Fox pattern. The light is to cost the parish £1,300 a-year.

The Portsmouth Town Council have accepted an offer of the Edison Electric Light Company for the lighting of a district for six months, at the cost of gas—light for light.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT. [April 24, 1883.]

ELECTRIC LIGHTING MEMORANDA.

A correspondent of the *Electrical Review* has written with the useful object of exposing a few of the difficulties which still exist in connection with electric lighting supply and measurement on an extensive scale. His method in treating this trouble is declared to be to dispel the assurance given by some "electrical eminences," as he calls them, in lectures and otherwise, that the arduous problem no longer remains to be solved. As a matter of fact, according to this contributor, in question are "of the same magnitude as existed seventy years ago in the lighting of streets with gas." Because "the key to the whole situation is still an unknown one, which has hitherto engaged, with little success, the minds of many physicists and electricians. He says further that Professors Ayrton and Perry have tried eight different methods of generation or distribution with this object, but they failed through disregarding economy. In fact, the determining factor in measurement, therefore, this writer appears to believe that almost everything yet remains to be done. Another correspondent in the same journal laments that after the expiration of a year from the last reign for electric lighting companies, and notwithstanding all the capital that has gone in this way, "it has not yet been shown to the public that even a small "tenement of twenty houses can be effectively lighted and "dependent upon a constant supply of 'electricity, in the "same way that they are with coal gas." He, too, thinks that electric lighting fails fair to be generally regarded as an exploded idea.

A new publication called *Health* has appeared, as though there were not enough journals devoted to medical and sanitary matters. In the first number we meet with this statement: "The electric light has been supplied to a Vienna "hospital. This is as things should be." Why? Because "the problem of ventilation will be in greater part solved "when the electric light comes into general use." This sample of lunacy or careless writing does not promise well for the medium of the new venture. One would suppose that if the ventilation of a hospital is so defective that the products of combustion of a few gas flames cannot be removed, the general health of the patients calls for some more drastic reform than the introduction of electric lighting. It is evident that in thoughtlessly approving the dismissal of one of the best aids to ventilation ever brought into a hospital, or anywhere else, our contemporary manifested more than a common share of youthful indiscretion.

It may be gathered from a few remarks recently made in the House of Commons by the First Commissioner of Works, that the expense to the nation of the experimental Edison lighting in the smoking-room and library has been overstated. The Company are doing the work for the remainder of the session at little more than the cost of the gas formerly consumed, which would be about £100, leaving the ultimate permanent adoption of the system in the option of the First Commissioner. The arrangement was explained in the House in reply to a question by Lord R. Churchill, who by the tone of his inquiries seems to have suspected the existence of a job in this selection without publicity of one firm of electricians.

Metropolitan (London) September, 1882.

Domestic Electric Lighting in America.—We learn by telegram that on Tuesday evening Mr. Edison's system of providing an incandescent electric light for domestic purposes throughout a given district was put to a practical test in the City of New York. The district selected occupies an area of nearly a square mile. One square mile of supply is provided, and that furnishes the illuminating power for sixteen thousand lamps, the electric current passing through eighteen miles of mains. The result, according to the latest dispatches, is that the seventy thousands which the consumers have been able to make upon the new supply have been satisfied. Throughout the district lighted each lamp is independent of all the others. It may be recollected that in the course of the last inquiry before the Select Commission of the House of Commons, Dr. Siemens said it was impossible to supply electricity for domestic lighting, from one source, over a greater area than a square quarter of a mile. On Tuesday night although only five thousand lamps were lighted in New York they were in distributed over the entire district of the square mile. We are told further that in the district there are fifteen hundred consumers of gas, of whom eleven hundred have subscribed for the electric light. It may be added that Mr. Edison is described as acting in his business operations on isolated plant on the same principle; and the managers assure our informant that they are quite satisfied in respect to the commercial aspect of the question. In a future issue we hope to be able to furnish our readers with full particulars of these interesting and important installations.

The Jablochkoff Electric Light Company have taken large premises on the Albert Embankment, to be used as a manufactory for their carbon candles, and warehouses, and as a lighting contractors' office, whose erecting a building on site of the Victoria Embankment for the purpose of more effectually carrying out the contract with the Metropolitan Board of Works. It is stated that numerous applications have been received for the supply of the Jablochkoff light, to meet the demand for which several powerful engines and electric machinery are about to be established.

Improved Public Lighting at Brighton.—Since the introduction of the electric light the Brighton Town Council have had under consideration the better lighting of the town by gas, and the Gas Committee now recommend the Council to increase the consumption of gas in a number of the principal streets from 4ft. per hour per lamp, to 6ft., and in a further list of streets of secondary importance to 5ft. per hour. The recommendation, if adopted, will result in an additional consumption of 2,672,278 cubic feet of gas per year, at a cost of £632. This, however, does not represent the sum that will have to be paid above that of last year. That year the price of gas is reduced from 3s. 6d. to 3s. 3d., thus effecting a saving of £592 13s. 9d. in the cost of public lighting. Deducting this from £632, the additional cost for the increased light will be only £111 4s. 3d.

Electric Lighting at Eastbourne—From Eastbourne we hear that on Saturday evening last the sea-front and gardens for nearly two miles were lit up with the electric light, and that the new means of illumination proved most successful.

ELECTRIC LIGHTING MEMORANDA.

The subscribers to the great Brush electric lighting installation on the Holborn Viaduct have received a courteous intimation from the Secretary of the United Swan and Edison Company, to the effect that the supply will soon be discontinued, and they are therefore requested to inform the Company when it will be convenient to have their services cut off. Thus ends the enterprise from which so much was expected, and which has done so little beyond keeping itself in existence at a cost that will never be repaid. Of course, it will be said that this stoppage is only a preliminary to a recommencement of operations elsewhere in a more favoured district. But it will occur to most people that the position occupied by the Holborn Viaduct on the Viaduct was as good as they can hope to find in any other part of London. It is a central site, on a thoroughfare provided with subways, whence the extension of supply into the most thickly populated and opulent part of the City was extraordinarily convenient. The whole of the City of London was open to the introduction of the incandescent system from this centre of supply. Wherefore, then, retreat with the road to victory clear? The Company's circular states that the installation was intended to prove the scientific possibility of supplying incandescent lighting, and this having been done—the curious method of signalling a triumph. The subscribers who went to considerable expense to adapt their interior fittings for the Edison system will, of course, lose their money, which will constitute their reward for the entertaining spirit they displayed, and the patience with which they endured the eccentricities of the light. Their fate will scarcely be an encouragement to the subjects of the next attempt on the part of the United Company.

The South African Bread Company has had a meeting last week at which the shareholders completely upset the proceedings of the Directors. It was an extraordinary general meeting, convened for the purpose of passing a resolution, originating with the Directors, for the reduction of the capital £50,000, so as to convert the existing 5s shares into shares of £2 10s, which would leave an unpaid liability of 10s. instead of £2 10s, as at present. In moving the resolution for this purpose, the Chairman made a speech of the usual character; boasting that the bread dynamo was the best in the world, and stating that the lighting done by the Company was Kimberley was much better than anything of the kind that had been done in England. It is remarkable how distance lends perfection, and perhaps "enchantment is to the view" of electric lighting. Failures and disappointment close at hand are always explained away, and everything is reported to be so much better somewhere else. English people used to be told by the earlier Brush prophets that the place to see their lights in perfection was America. In the United States, the successes of the English electricians were equally held up to admiration. Not long since the Company of The Times stated that electric lighting in particular could only be seen to perfection at Mr. Phillipart recently informed the shareholders of his Accumulator Company that the Faure-Sellon-Volckmar batteries could drive tramcars in Paris better than in England. Now we are informed that the best display of South African Brush shareholders, however, seemed to think that the game was played out; and they declined to allow the Board to lavish the unrefilled balance of 10s. per share. They submitted an amendment, in the teeth of the Chairman's and his friends'; and as this was not put from the chair, they contemptuously rejected the Directors' motion. A poll was demanded, but, whatever may be the result, it is evident that the working days of the speculation are numbered, as the shareholders seem determined to enforce a return of so much of the capital as can be saved.

The public of New York have apparently awakened to the evil of allowing electric lighting companies to string their lines all over the city without restrictions based on considerations of safety for life and property, and have been told by many authorities that the only possible course to be followed is to compel the electric companies to put all their cables underground. The *Sanitary Engineer* recently summed up the prevailing idea, by declaring that electric lighting was not so much a necessity for social existence that the dangers of the exposed wires could be endured for its sake. The companies are therefore bidden to bury their cables; and when they reply that they cannot do this and live, the alternative is accepted with almost brutal candour. Meanwhile, however, it has been overlooked that underground wires are quite as dangerous as the others. This view of the case has been presented to the American public by Professor Sperry Morton, in a letter which is a model of its kind. He shows that of all the systems of electric lighting in use in New York, the Edison Company—with their underground wires and low tension currents—are chargeable with having caused the greatest damage. It is true that the total amount of injury to life or property from this cause is said to be insignificant; but it is a curious fact that "more than seven times as great loss has occurred from the 10 miles of underground wires than from the 800 odd miles of aerial wires, although the latter have been much longer in use." Professor Morton thinks that the chances of accidental contact with the wires would always be greater when the latter are underground. From the point of view of the companies, it is manifest that "it is impossible to carry on successful electric lighting on an extensive commercial scale with underground conductors," because of the expense. Professor Morton's ideal solution of the difficulty is the construction of subways—which postpones the satisfactory introduction of electric lighting to the millennium of the sanitary reformer.

The Metropolitan (London.) July 12.

Cost of the Electric Light.—Messrs. Samuel Brothers, of Ludgate-hill, have published some details concerning the electric light as employed upon their establishment. The dynamo machine is worked by an Otto gas engine of 3 horse power, which, when new, is in excess of what is required for the existing lights, and would be amply sufficient for a number of incandescent lamps which are about to be fitted up in the counting-house, private office, and fitting-room. The replaced lamps require no skilled attendance, and are attended to by the head porter. There are altogether 80 "Jablochkoff" arc lights, five of which are in the front, and the remainder are employed to light up 4,000 square feet of space inside. Each lamp has an illuminating power of 378 candles, equal to 35 ordinary gas burners, as verified by the scientific staff of the Jablochkoff Company, and when new the "Jablochkoff candle" consumed more than one penny per hour, and the gas consumed by the Otto engine costs only one penny per 5 amp. per hour. The total expenditure for arc lamps is £150, the lighting of the premises averaging three hours each night.

A keen competition is at present going on in Manchester between the gas and electric systems of lighting. The Manchester Royal Exchange is being lighted by the British Electric Company with 200 incandescent lamps.

The price of gas at Selkirk has been reduced from 4s. 7d. to 4s. 2d. per 1,000 feet.

The directors of the Brush Midland Electric Light and Power Company (Limited), have decided not to raise the call of £1 per share fixed for July 1, as sufficient capital is in hand for present requirements.

The Metropolitan (Brush) Electric Light and Power Company are now making a vigorous start, and already possess stations in Holborn and Westminster. They are receiving applications for their system of lighting from all parts of the metropolis, and intend, as rapidly as possible, to open out stations throughout the whole of the metropolitan postal districts.

THE METROPOLITAN.

The Electric Lighting Bill.—So far as general principles are concerned, the Select Committee appointed by the House of Commons to consider the various electric lighting schemes before Parliament this Session, and especially the Bill introduced by the President of the Board of Trade, have practically concluded their labours. The taking of evidence was completed by the middle of last week, and on Thursday afternoon the chairman announced that although the committee would meet again to determine on other certain points in respect of which they had not then come to a decision, they had absolutely determined to recommend the House to strike out of all Bills that have been presented this Session every reference to electric lighting. The committee met again on the following day, and, after further deliberation, the chairman stated to those present that the committee had passed fifteen resolutions embodying their conclusions in regard to the lines upon which they would recommend the House to amend the fifth of the Board of Trade. These resolutions are given below, and it will be at once seen that the Board of Trade proposals have in the main been accepted. The committee have adjourned until the 8th inst., to hear any arguments against Mr. Chamberlain's Bill as amended, but it is understood that they will not hear further arguments or evidence contrary to the principle of the resolutions. In our next week's issue we shall probably examine at some length the evidence submitted to the committee in the course of the inquiry, and consider the practical working of the powers proposed to be conferred upon the Board of Trade. For our own part we are not at present over-confident that the result of the committee's investigations, so far, is all that might be desired in the interests of the public. The President of which the committee have acted are apparently viewed with satisfaction by the gas interest, and that is a matter of suspicion.

The following are the resolutions adopted by the Committee of the House of Commons:—

1. That the Board of Trade be empowered to grant licences to local authorities, or to private undertakers, with the consent of such local authorities, to supply electricity within a defined area.

2. That such licences be for any period not exceeding five years, but may, at the expiration of the licence, be renewable with such consent as aforesaid.

3. That the Board of Trade be empowered to grant provisional orders, in addition to licences to private undertakers, without the consent of the local authorities, for the supply of electricity; but such provisional orders shall be subject to confirmation by Parliament.

4. That notice of any application for a license or provisional order be given by public advertisement in the district, and full opportunity be given to all parties interested to object to the grant of the license or Order.

5. That no application for a license or provisional order be granted until the expiration of three months from the notice of such application.

6. That no application by any local authority, for a provisional order under this Act, be proceeded with until it has been submitted to a meeting of the local authority, specially convened for the purpose by public notice.

7. That licences and provisional orders should carry with them a power to break up the streets for the purpose of laying the necessary mains.

8. That where it has been proved to the satisfaction of the Board of Trade that the area as defined by the Electric Lighting Order, is sufficiently supplied with electric light, and that the supply of gas has been proved to be unnecessary, the Board of Trade be empowered to make an order relieving, either wholly or in part, any corporation or gas authority from being compelled to supply gas within such area.

9. That local authorities be empowered to purchase compulsorily the undertaking of any company or persons authorised by provisional order to supply electricity at the end of 21 years, or at the end of any subsequent period of seven years.

10. That for the purpose of the purchase of the undertaking, the value of the land, buildings, materials, and plant, shall be deemed to be their fair market value at the time of purchase (due regard being had to their nature and their condition in their state of repair, to their suitability to the purposes of the undertaking, and (where a part only of the undertaking is purchased) to any loss occasioned by severance, but without any addition in respect of compulsory purchase, or of goodwill, or of any past or future profits, or of any similar consideration.

11. That licences and Provisional Orders should contain such regulations—(a) For securing the safety of the public from injury to life, or limb, for (b) the supplying of the undertaking a regular and efficient supply of electricity; (c) for fair rating; and generally, any power to be necessary; and where it has been found by the Board of Trade that public safety is likely to be endangered, that in all times there power to make such further regulations as may be required for securing the safety of the public.

12. That overhead wires be forbidden without the consent of the local authority, and where it has been proved to the satisfaction of two justices of the peace, or corresponding authority that any such wire is, or is likely to become dangerous to the public safety, they may make an order directing it to be removed upon such terms as they may think fit.

13. That local authorities supplying the electric light be required to keep separate accounts of such undertaking, and to publish them in detail for the information of the ratepayers.

14. That the Board of Trade be required to submit to Parliament an annual report of their proceedings under this Act.

15. That any undertaking which could be authorised by private Acts for the supply of electricity be subject to the conditions contained in this Act.

The Electric Light Company has secured the premises and machinery lately used by the Electrozone Manufacturing Company, and from thence the electricity will shortly be supplied for the purpose of lighting the Strand and the New Law Courts.

Messrs. Waterhouse and Winterbotham, solicitors to the Edison Electric Light Company, have written stating that the Swan incandescent lamp is an infringement of the Edison patents.

The Metropolitan (London.) June 24th, 1882.

We understand that Major Flood Page has resigned the post of manager of the Crystal Palace, and has accepted that of general manager of the Edison Indian and Colonial Electric Light Company.

Electric Lighting at Stafford House.—The electric lighting of Stafford House, the noble residence now leased to a very large party of guests by the Duke of Sutherland, will take its rank amongst the most efficient examples of the incandescent system. The work has been carried out by the British Electric Light Company, and from end to end and on the sixth floor midnight the staff consists of twenty-one-pair coals, were maintained with perfect steadiness and regularity, and with no perceptible heat in the large hanging lamps in the saloons, the noble picture gallery, 120 feet long, and the grand staircase. The total number (116) of the electric lights dispersed in numerous candelabra without a vestige of the conducting wires being anywhere visible, and the banqueting room, 60 feet in length and equally ample in its other proportions, was similarly fitted up, and equally ample in its results. Dynamos worked in duplicate, and of 30 horse power, were erected in the engine-room and manages; and not the least remarkable of these was a single 4-horse-power engine, which is used effectively a considerable portion of the garden. The motive power is a 20 horse-power Marshall engine, and there exhibited were three eight dynamos machines and two feeders. The machinery is altogether well planned and erected, running noiselessly, and with perfect regularity. The system of distribution of the current is excellent, and the working effective, and exhibits every appearance of prudence and simplicity. All the machines send their currents into one main conductor, and the nature of the currents is such that there is no danger to assistant of the hands with the unprotected wires. The switches are so arranged that each set can be cut off separately, and the lights in any of them further power can instantly be obtained from the main. The only apparent objection of one plug in a room of five or six; and if one socket should go wrong, the other feeders which is running vacant can be at once utilised, and the work be done. These arrangements and the beauty and steadiness of the lights were much admired. The Duke personally conducted his numerous guests, amongst whom were Sir Charles Bright, Mr. Siemens, Sir Samuel Canning, Mr. Crookes, F.R.S., and other eminent electricians; the Director of Military, General Campbell, K.C.B., &c.

Electric Lighting at the Crystal Palace.—The Crystal Palace authorities have decided to continue the lighting of the terrace throughout the summer months by the Jablochkoff electric lighting, and have sanctioned the extension of this system over the track of the new Electric Railway, which is about to be opened in the grounds.

Metropolitan (London) July 1, 82.

Electric Light and Power Generator Company.

The first annual meeting of the shareholders of this company was held at the Cannon-street Hotel on Tuesday, Admiral Sir E. A. Inglefield, C.B., F.R.S. (chairman), presided.

The report, stated that the total sum received for preliminary expenses, commissions, and underwriting, &c., was £6,669; that the amount spent on patents and experiments, work and improvements, was £9,806; and that the total expenditure for salaries, fees, and general charges, was £1,811, leaving a small sum of £6,052. Since the last meeting the directors had purchased the Wood and Maxim patents of electric lighting, each of which systems the directors believed to be second to none, and had fully answered their expectations. The endeavours of the directors during the past year, under review had been successfully applied to the dissemination of a knowledge of the above-mentioned systems throughout the country. A very favourable contract had been made with the Railway and Electric Appliances Company (Limited), and with the Islington Company. A second contract had also been made with the Commissioners of Sewers for the City, and others were confidently expected. Altogether the company possessed a valuable property, which, if carefully managed, must prove highly remunerative, and, he trusted, for a patent to be a good one and to be well worked without its being immediately remunerative to its possessor.

It was his duty to prove that the validity and excellence of their patents were unquestionable, and that the directors had done their utmost to make them remunerative. At the time that the company took over the patents they had been given to them by the City authorities for the lighting of a portion of the City, they had only the Lontin light. They intended to produce the light by May, 1883, at the rate of 40/- a month. They commenced literally without staff, workshops, or stores. They had, however, found premises near Southwark-bridge, where they secured. After the chairman explained the method of applying the light, the directors offered the incandescent lamp now well known to the Maxim light, and they were advised not to accept it for the chance of obtaining the price asked was very large, £100,000. The directors accepted it on receiving shares to the value of £54,000, of which £52,000 was to be paid in shares, and £2,000 in cash. Part of the agreement was that the company should also purchase the Wallace-Dick light, with a number of patents with it, which of course was to be paid for by a fresh issue of shares. The directors, however, had not yet completed those arrangements, as they were awaiting the result of experiments which were being made in America. The Lontin light was found to work best in the streets selected by the company, viz.: Queen Victoria-street, Queen-street, Cheapside, and Newman-street, Oxford-street. All of these places were worked from the station near Southwark-bridge, but the light during the season of long days was not in request, and it was found that it was carried also with less "noise" burning. This operation was found to be dangerous in the extreme, and the current was ceased. Immediately after the meeting the directors decided to store the light temporarily rather than sell it at a sacrifice. This difficulty, however, had been obviated by the use of double arc lamps, some of which they intended to employ in the City streets, and some of which they hoped to complete in the City premises. The Lontin light had been tried, and the result was successful. (Applause.) The chairman went on to describe the connections the company was preparing to grant to other companies, from which they expected a profit of £60,000 in one year. The company had secured the fifth in the gold ore of the Cooking, F.R.S., explained the position. Mr. Woodward seconded—Mr. W. Electrician to the company, and the circumstances under which he had said in the early days of the company. He said he was pleased at the favourable position of another company, which would relieve them to introduce their own. He was quite willing to resign his position, but he was bound to say that the success of the company was due to the energy and ability of the chairman. Sir Mr. Crookes had resigned with grace, as he was pleased to have been able to aid him so far. The report was then adopted. The retiring directors, Sir E. Inglefield and Sir H. Smith, were re-elected. Mr. Woodward, Mr. H. Davey, and Mr. Hedgeland were elected. A short extraordinary meeting was next took place for the purpose of changing the name of the company to "The Anglo-Varley Electric Light Company (Limited)." In proposing this, the Chairman (Sir E. Inglefield) was the more readily because the first started, the name, twenty-three electric companies had adopted the word "Light and Power," and one company had adopted the word "Electric Light Generating Company," which was only one syllable different to theirs. The alteration proposed would at once show the difference to opposites which the company possessed. The resolution was carried unanimously, and the meeting terminated with a vote of thanks to the chairman.

July 25, 82.

THE METROPOLITAN.

Electric Lighting in the City.—We have pleasure in giving insertion to the following communication:—

TO THE EDITOR OF THE METROPOLITAN.

SIR,—In your quotation of the 19th inst., you did me the honour to allude to a letter of mine published by a contemporary upon this subject, and as in the following remarks I have detailed the comparison of the cost of electric and gas lights as the principal consideration, you may consider them of sufficient interest to many of your readers to induce you to publish them. In the first statement of facts in the letter referred to, I showed the comparative cost of the electric and gas lights *per se*, and in the second the relative cost of the leading interest and depreciation of plant, &c., between the electric, and the latter result is the one which more particularly concerns the ratepayers and the possible users of electricity. In the concluding paragraph of my letter, I alluded to the greatly increased [illegible] of the electric illuminating power—and in explanation I would now say it is stated that the official report presented to the Commissioners of Sewers in 1881 that the illuminating power of the electric light supplied under the former contract was equivalent to be 100 Electric Jabloschkoff (Brush) 15 times illuminating power to be 100 Electric Jablochkoff (Brush) 15 times illuminating power to be 100 Electric Jablochkoff (Swan) 15 times, and in Electric the Victoria Embankment, an intense or open arc average 165 times that of the ordinary gas lamps with which the former comparisons of cost were made. In the former communication I quoted the present cost of gas in five districts to be £3/8/, against the lowest tender for electricity in those districts to be £3/8/, against the should be added interest and depreciation upon the cost of works and installation, which would increase the amount charge to £3/18/, or an addition of 10 per cent. upon the cost of gas, but for which a light possessing 165 times the illuminating power would be obtained. The power would also be much more illuminating—that measure for measure making the electric light of this power about one-eighth the price of gas for the same power, when obtained. In confirmation of these results I may add that the Hammond Electric Light Company offered to light the Strand district for £3,000 per annum, exclusive of the cost of installation (amounting to £7,250 and therefore equal to 40 per cent. and depreciation) the annual cost of which would be £2,775, or a little in excess of the lowest tender for electricity.

Since the introduction of the electric light much ingenuity has been exercised on the production of improvements in gas, and the result is in many cases very satisfactory, but, of course, the consumption of gas is increased. Some of the new burners, which give five times the quantity of gas, but probably not five times the light, have been tried in the Strand district, and the result would be £5,211 per annum (exclusive of any allowance for the new burners and times) for six times the illuminating power, equal to 1,000 gas lamps, which is a saving in such a case of £1,564 (or 30 per cent.) upon the illuminating power, or, say, 16½ per cent. upon the illuminating power, or, say, 16½ per cent. upon the illuminating power, or, say, 16½ per cent.

tions which may be contained in any such license, order, or special Act in relation thereto." Any time authority within any part of whose district electricity is authorized to be supplied, may, in addition to any regulations which may be made under the preceding provisions of the section for securing the safety of the public, from time to time make, rescind, alter, or repeal byelaws for further securing such safety; and there may be annexed to any breach of such byelaws such penalty not exceeding forty shillings for each offence as they may think necessary: Provided that no such byelaws shall have any effect unless confirmed by the Board of Trade and published.

7. Any expenses incurred by a local authority under this Act, and not otherwise provided for, may, be defrayed out of the local rate, and the local authority may from time to time issue such rates to be levied as may be necessary for the purpose of defraying such expenses.

8. A local authority authorised to supply electricity by any license, order, or special Act may from time to time borrow money for such purposes. Where any local authority is authorised by any Act to raise any money which they may be empowered to borrow for certain purposes by the issue of corporation or other stock, any money which a local authority may be authorised to borrow under this section may, if it is thought fit, be raised by them by the issue of such stock as aforesaid. This section shall apply to the Metropolitan Board of Works, except in so far as the Metropolitan Board of Works may be concerned in the borrowing of any money by any Vestry or District Board.

9. The provisions of the Companies Act, 1862, with respect to the audit of accounts annually, and shall sell copies of such annual balance sheet to any applicant at a price not exceeding one shilling a copy.

10. The undertakers may, subject to the provisions of the Act and for the purpose of supplying electricity, acquire such lands by agreement, construct such works, acquire such licenses for the use of any patented inventions, purchase inventions, machinery, apparatus, methods, materials, or other things, and such rights, powers, and privileges of all such acts and things as may be necessary and incidental to such supply.

11. Any local authority who have obtained a license, order, or special Act for the supply of electricity, may contract with any company or person for the supply of electricity within their district required for the purposes of such supply, or for the use of any electricity or meters belonging to such company or person by any special Act, or in any part of such area; but no local authority, company, or person shall by any contract or assignment transfer to any other company or person, or divest themselves of any legal powers given to them, or any legal liabilities imposed on them by this Act, or by any license, order, or special Act, without the consent of the Board of Trade.

12. The provisions of certain sections of the Lands Clauses Acts, the Gasworks Clauses Act, 1847, and the Gasworks Clauses Act, 1871, shall be incorporated with this Act. All offences, forfeitures, penalties, and damages under the said incorporated provisions of the said Acts or any of them may be prosecuted and be recovered in like manner as if the Acts respectively enacted the offences therein.

13. Nothing in this Act or in any Act incorporated therewith shall authorise or empower the undertakers to break up any street which is not repairable by such local authority, or any railway or tramway, without the consent of the authority, company, or person by whom such street, railway, or tramway is repairable, unless in the case of a street repairable by a corporation, where in a license, order, or special Act, or with the written consent of the Board of Trade, such consent shall not give any such consent until an opportunity has been given to such authority, company, or person to state any objections they may have thereto.

14. Notwithstanding anything in this Act contained, the undertakers shall not be entitled to place or keep any of the above ground, post, arm, or stanza set street, without the consent of the local authority, and the local authority may require the undertakers to forthwith remove any electric line placed by them contrary to the provisions of this section, or to alter or remove the same, and reinstate the expenses of such removal from the undertakers, a summary order for the same may be made by any court of summary jurisdiction on the application of any person aggrieved, and such electric line is or is likely to become dangerous to the public safety, may, notwithstanding any such consent as aforesaid, make an order directing and authorising the removal of such electric line by such person and upon such terms as they may think fit.

15. Subject to the provisions of this Act, and subject also to further specified conditions, the undertakers may alter the position of any pipes or wires below, above, or over any place authorised to be broken up by them, and may interfere with the exercise of any company, or person may in like manner alter the position of any electric lines or works of the undertakers, being under any street or place as aforesaid, which may interfere with the lawful exercise of any powers vested in such local authority, company, or person in relation to such street or place, subject to the conditions and restrictions

16. This is a clause for the protection of canals.

17. In the exercise of the powers in relation to the execution of works given them under the Act, the undertakers shall make full compensation to all bodies and persons interested for all damage sustained by them by reason or in consequence of the exercise of such powers, the amount and application of such compensation in case of difference to be determined, in arbitration as a supply on the terms and conditions of the Lands Clauses Acts.

18. The undertakers shall not be entitled to prescribe any special form of lamp or burner to be used by any consumer or person, or in any way to control or interfere with the manner in which electricity supplied by them is used, provided always that no local authority, company, or person shall be at liberty to use the electricity supplied to it by the undertakers for any purpose, or in any manner or so as unduly or improperly interfere with the supply of electricity by the undertakers to any other local authority, company, or person.

19. Where a supply of electricity is provided in any particular area for private purposes, every company or person within that part of the area shall be entitled, on application to the undertakers, and upon terms on which any other company or person in such part of the area is entitled under similar circumstances to a corresponding supply.

20. The undertakers shall make such charges for the supply of electricity, to any such agreed upon, not exceeding the limits of price imposed by or in pursuance of the license, order, or special Act authorising them to supply electricity.

21. The undertakers may cut off the supply in cases of non-payment of charges for electricity.

22. Any person who unlawfully and maliciously cuts or injures any electric line or work shall be guilty of felony and liable to punishment accordingly.

23. Provides for punishment of persons stealing electricity.

24. Any officer appointed by the undertakers may at all reasonable times enter any premises to which electricity is or has been supplied by the undertakers, in order to inspect the electric lines, meters, transformers, fittings, works, and apparatus for the supply of electricity belonging to the undertakers, and for the purpose of ascertaining the quantity of electricity consumed or supplied, or where a supply of electricity is no longer required, or where the undertakers are entitled to take away and cut off the supply of electricity from any premises, for the purpose of removing any electric lines, accumulators, meters, or other apparatus belonging to the undertakers, repairing all damage caused by the removal thereof, or accruing.

25. Electric lines, &c., not to be subject to distress in certain cases.

26. This clause provides for the protection of the property of the Postmaster-General.

27. Where any undertakers are authorised by a provisional order or special Act to supply electricity within any area, any local authority within whose jurisdiction such area or any part thereof is situated may, within six months after the expiration of a period of twenty-one years, or such shorter period as is specified in that behalf in the application for the provisional order or in the special Act, from the date of the passing of the Act confirming such provisional order, or of the special Act, and within six months after the expiration of every subsequent period of seven years, or such shorter period as is specified in that behalf in the application for the provisional order or in the special Act, by notice in writing to the undertakers purchase, or at their option require the undertakers shall sell to them their undertaking, or so much of the same as may be within such jurisdiction, upon terms of paying for the value of all lands, buildings, works, materials, and plant of such undertaking wholly or mainly used by them for the purposes of their undertaking within such jurisdiction, such value to be in case of difference, to be determined by arbitration, and in the case of such lands, buildings, works, materials, and plant shall be deemed to be their fair market value at the time of the purchase, but regard being had to the nature and then condition of such lands, buildings, works, materials, and plant, to the state of repair thereof, and the suitability of the same to the purposes of the undertaking, and, where only part of the undertaking is purchased by severance but without any additional consideration in respect of compulsory purchase, or otherwise, of any lands, buildings, or plant which have been or be made from the undertaking, or of any similar consideration. The Board of Trade may determine any other questions which may arise in relation to such purchase, and may fix the time within which the purchase is to take effect, and from and after the date so fixed, or such other date as may be agreed upon between the parties, all such lands, buildings, works, materials, and plant as aforesaid shall vest in the local authority which has made the purchase, free from any mortgage, or similar charge affecting the same, but nothing in the undertaking, and the powers of such undertakers or attaching to the undertaking, and the powers of such undertakers in relation to the supply of electricity in the area of such provisional order or special Act as aforesaid within such area, and not thereof as aforesaid shall absolutely cease and determine, and shall vest in the local authority aforesaid.

28. Where any matter is directed to be determined by arbitration, such matter shall, except as otherwise expressly provided, be determined by an engineer or other fit person to be nominated as arbitrator by the Board of Trade.

29. Where a supply of electricity is authorised in any area within such area or any part thereof, such gas undertakers being under no obligation to supply gas upon demand, the Board of Trade may make an order directing that such gas undertakers may, in any district within such area, either wholly or in part, and upon such terms and conditions as they may think proper,

30. The Board of Trade shall report annually their proceedings under this Act.

31-33. These are interpretation clauses.

34. This is the clause for the protection of mines.

35. The undertakers or their undertaking shall not be exempt from the provisions of any general Act relating to the supply of electricity which may be passed in this or any future session.

36. Nothing in this Act shall affect the duty, license, duties, or special Act, or the exclusive privileges conferred upon the Postmaster-General by the Telegraph Act, 1869.

37 and 37. This Act shall apply to Scotland and Ireland with certain modifications.

August 26, 1882.

THE METROPOLITAN.

The Edison Light at the General Post-office.—An interesting and important installation of the Edison system of electric lighting has been completed at the General Post-office, and on Monday evening the 21st it was formally opened for public inspection. The large building on the western side of St. Martin's-le-Grand was illuminated by means of sixty Edison lamps. As our readers are aware, the Holborn-viaduct and many of the shops and business premises in the immediate vicinity have, for some time past, been lighted by the Edison Company from a central station, which has been established in a building situated a few doors from the village pump in Farringdon-street. The same system serves to supply the electricity for the rainbow-dance of the Alhambra, and, if we mistake not, the Criterion, we believe, is the greatest that has yet been made by Mr. Edison's representatives in this country from one centre, the distance from the dynamo-room on the Viaduct to the "Press-room" in St. Martin-le-Grand being 1,050ft. The importance of the work thus accomplished is obvious. The company claim that they can work in circles of half a mile radius, and the mile from Holborn-viaduct will include St. Paul's and the district around it, Blackfriars, part of Fleet-street, an important part of Holborn, including the Circus, the Mansion-house, and the whole of Cannon-street. The "Press-room" to which the Edison electric light has thus been supplied is a very busy one, and is used to afford our readers some further particulars of the same. As everybody knows, various attempts have been made to employ batteries for the production of the electric light, with more or less favourable results, but up to the present time it is not unsafe that a light has been obtained by this means possessing either the stability or the adaptability requisite in a light for every-day use, or produced at a cost at all comparable with that at which gas is, as a general rule, available. Mr. Crompton, we have learned a battery which he claims is entirely new in every particular, and which, he says, will supply every requirement so far as ordinary interior lighting is concerned. The invention is the subject of three distinct specifications, relating respectively to the battery, the fluid employed, and the special construction of the holding batteries. The object has been to provide a system of lighting which, while being used in large or small houses and of being easily managed by the most unskilled in matter mechanical, shall be entirely free from danger, and to meet the assumption that if the electric light is only to be obtained by the firing of a dynamo machine and engine on the consumer's premises, or even from a central station, the cost would be too great to be remunerative, there must be a very promising future for a method of rendering the light possessed by each accumulator as those claimed for this particular system. The invention relates to a fluid for the charging or construction of what the author terms a multiple carbon battery, the idea being to obtain greater constancy and electro motive force than hitherto, and also to the provision of improved means for filling and discharging the cells. Mr. Crod asserts that by the employment of his batteries any number of lights may be maintained for a period ranging from forty to sixty hours, without the batteries requiring to be recharged, and he says further that there is not another volaic battery in existence that will produce equal results, ingeniously conveyed as a means of checking accident from any increase of current; as the load, with any increase of heat, would melt, and thus extinguish the lamp herewith. The work of separating the "Press-room" of the Post-office from the electric light was carried out in about ten days. It may be added, as a matter of interest in connection with the Edison system, that the model exhibited at the Paris and America by the Edison Company, the wires for supplying the building between Gerrard-street and Shaftesbury-avenue having been laid down in the streets, and everything working on the ever-ready principle. The electric light, it is said, has been of a most satisfactory nature, and the secretary of the company writes that during the first week in September, the electric light will be simultaneously in up.

The Economy of the Electric Light.—According to the report of Lieut.-Col. Fenwick, R.E., the assistant director, especially entrusted with the charge of the Museum buildings, South Kensington, the employment of the electric light instead of gas, in certain portions of the Museum, has resulted in a considerable saving. In his report, issued some months ago, Col. Fesling stated that for some time previously the Lord President's Court had been lighted by means of sixteen Brush lamps. We now learn that since May he Raphael and Sheepshanks rooms have been lighted, as well as Lord Presidents' Court, and seven additional lamps being employed, making thirty-two in all. The working of an engine has been amply borne out. The machines and engine belonging to the Industrial Society, Limited, are illuminated by and the consumption of coal per hour of work is 7lbs. per horse power. Each lamp burns about 10 hours, when there were only 16 wages, as far as the only addition to this head has been for the additional attendance to this head has been for the additional attendance to this head has been for the additional attendance

It appears that the light obtained by means of this invention has recently been subjected to a series of photometrical tests by an electrician, Mr. Swinburne. Using a 5 day or two gaps, in an of practical a character, and so clearly and impartially states the present position of the matter as between the two rival modes of lighting, that we offer no apology for reprinting it *en masse* :—

Sir,—In the present state of uncertainty existing in the minds of many of the public as to whether the time has yet arrived for it to be prudent to incur the expense of substituting the electric light for gas in private houses, I send for your inspection some particulars of the lighting by electricity of a house I have recently had fitted in the way I set down for it.

Berechurch Hall is about three miles from Colchester, and in the latter end of last spring I determined to go into the whole question of the best and cheapest method of illuminating it. I had at that first instance an estimate drawn up of the cost of laying down gas plant, which was simple enough; but when I came to that of the electric light many difficulties presented themselves. Not only was there the widest divergence as to cost in the tenders sent in, but I found that it would be necessary for me to be acquainted with the various kinds of lights, the relative merits of the dynamo machines, the best kind of engine to drive them, whether accumulators should be employed, the manner in which the wires should be laid down, where they should be laid in the house, the precautions to be taken to prevent risk of fire, &c.; for upon all these the permanent value of the installation appears to depend. I saw at once that I would be reckless as well as economical to employ professional assistance. I therefore engaged the services of Mr. Heaphy, C.E., of the Phœnix Electric Office, to advise me upon the matter and superintend the installation of the plant. Mr. Heaphy is also engaged on different systems of lighting, the result being that I determined to adopt the Swan incandescent light. Mr. Heaphy is making a report to accompany the tenders of Messrs. Crompton and Co., to supply the same, after I had decided upon it. Mr. Heaphy is also up a regular specification and contract going into every detail, and giving me the power of rejecting any work or materials he was not perfectly satisfied with. We were arranged to have 200 lights of 16-candle power each, and four dynamos to supply them. As regards the latter, I have a preference for Crompton and Co.'s engine as it is a horse power less and wires to be handled, and the other details are the most possible ones. They were to be embedded in the floor—not unfrequently inside the rooms, from each other, and also from the floor of the room above, and the upper floor, every room, and, in short, every kind of metallic substance, excepting the wires themselves and the lamps, each light to be put in quasi equilibrium overhanging of the wires, as well as a leaf "cut out" of the ceiling.

The whole has been carried out as specified, and the result has been a success that has exceeded my expectations. The plant is quite as easy to manage as gas, and the witness, the purity, and the agreeableness are such that a return to any other method of illumination would be quite out of the question. The pictures, walls remain unsullied, while the cleaning of lamps, chandeliers and for an evening in a room electrically illuminated is lighted by gas, must be experienced before it can be appreciated.

I will now give details as to cost :—Estimate for gas plant, pipes in house, £200; cutting and making good walls and floors, £25; laying gas and brackets, £30. Total, £255. Estimate for gas plant, dynamo machine, £165; 150 lamps, £75; 2 switch boards, £10; 2 resistance coils, £5; 2 voltmeters, £5; 2 ammeters, £5; 2 governors, £6; 2 sets of spring good walls and floors, £25; laying wires in house, £60; cutting and making good walls and floors, £20; 2 counter-shafting, £25; foundations to engine and dynamos, £15; chandeliers, lacing wires, &c., and carriage, £30. Total, £456. The cost of the latter is nearly for the whole of the buildings, £201 more. The excess of the same for gas 1 has then 1 have no nuisance of flues, no smell in the manufactory, or damaged to my garden; and, in the event of an engine breakdown, I have to compound like engine, placed out of view, and which, when not driving the dynamos, could be utilised for pumping water to the top of the house, and can also be employed for sawing wood, or any other purpose of a like nature, employed for sawing wood, or any other purpose of a like nature.

I will now enlarge upon the annual working expenses, and, in making a comparison, I will assume that it would cost the same to manufacture 1,000 cubic feet of gas at Berechurch as it does here.

Electric light—200 18-candle power lamps, each working 1,825 hours per annum.—Cost of 200, per cm. £38 10s. 1d.; engine driver at 30s. per week, £78; record of hours, £3 5s. 0d.; engine driver depreciation 5s per cent., cost of machinery, £71; depreciation 5 per cent. on conductors, £7; total, £429 15s. 1d.

Now, for less than half this amount of light it costs me £200 expense when I say that, had I used gas at Berechurch giving an equivalent illuminating power, it would have cost me at least £200 per annum to produce.

This would show an annual saving of £171 15s. 11d. to me by using electricity. Having had 30 years' experience of lighting this house by gas—which, I consider a great improvement upon any previously known method—I am only too sensible of its drawbacks and, although I am not easily satisfied with a new light, I am well satisfied that I have adopted electricity at Berechurch.

I am, Sir, yours truly,
OCTAVIUS E. COOPE.

Rochets, Berechurch, Jan. 11.

Electric Lighting Companies.—A very elaborate and comprehensive return concerning electric lighting companies has recently been published in the form of a special supplement to the *Mercantile Shipping Register and Colonial Merchant Review*. It gives full details of the constitution, progress and resources of all the companies, with explanatory tables and remarks, which afford a financial history of their public and private life from their birth to the present time. As the aim of the authors has been simply to state facts, and to avoid making invidious distinctions by proportioning selves without comment; but to facilitate comparison and the formation of a just conception of the whole, the leading facts have been summarised in the form of tables, to only one of which, however, we are able to allude. This table, which is of an exceedingly interesting and instructive nature, is divided into four sections and a summary; the first deals solely with the British Companies, of which there are no less than twenty; the second relates to companies that are actually at work, or prepared to work, and of these there are twenty-three, or only three more than the Brush list; the third refers to companies that do not appear to have been proceeded with practically; and the fourth to companies mostly recent, about which information is wanting or not yet attainable. The first point to which attention is called in the extract to which the companies are indebted to their shareholders. The figures show that the total of the nominal capital issued, £2,288,834, was 41 per cent. of the nominal capital of the companies comprised in Groups I., II., and III. of the first section, of those comprised in Groups I., II., and III. of this issued moiety 25 per cent. has been allotted and fully paid up to vendors, &c., leaving 60 per cent.—*i.e.*, under 75 per cent. of the whole nominal amount—to be paid up by the public. Roughly, eleven twenty-thirds of this has already been paid, which is to say, in the case of these companies, which do not include syndicates, agency, or provisional associations, a sum equal to 11 per cent. of the total registered capital represents the actual amount of public money received, while 5 per cent. or the same amount forms the extent of liability on future possible calls. This is a total nominal capital of something under twenty-five millions sterling, less than two millions and three-quarters has been *bona fide* invested, while the amount of shareholders' indebtedness stands at a trifle over three millions. The next point shown by the, Tables is the amount that has been received by the inventors and the promoters. The cash consideration is less little over a million, or (excluding Group IV.) £1,060,645. The shares allotted to vendors, as fully or partially paid up, form a more important item, and one specially onerous to shareholders, for it will be observed that the liquidating nature of payments to vendors, a sum of but £1,141,091 is left as working capital to earn a dividend upon £3,356,670 share capital. In other words, to pay a 5 per cent. dividend all round, over 15 per cent. must be earned upon the money actually employed in the business. Even if all calls were made and paid, and the whole issued as working capital, even so per cent. would have to be earned. This return, as might have been expected, is somewhat startling to companies in good circles, and it has not unnaturally been argued that the figures given indicate a condition of affairs which should inspire the public with confidence in gas stock. We anticipate, however, that in the minds of many the facts and figures given will be deemed capable of a very different interpretation, especially when the circumstances under which each few of these companies were established are borne in mind.

Electrical Exhibition at the Royal Aquarium.—We understand that Mr. Maginess Heaphy, C.E., has been appointed to report upon the fire risk of the Exhibition, and has already inspected the installations as far as they have progressed, and given detailed instructions as to the safeguards to be adopted. All the electric companies will be glad to learn that it has been placed in his hands, Mr. Heaphy being not only a practical electrician himself, and having had the superintendence of later installations, but he possesses great knowledge and experience on all matters connected with fire risk, particularly that of hazardous buildings, a combination of knowledge at present absolutely unique. The fair and impartial course Mr. Heaphy has taken towards electric lighting, while never losing sight of the interests of the fire offices, has excited great confidence in the minds of the electric companies whose work he has had to officially inspect. His rules and regulations are very well known, and have undergone little, but what is not generally known that the fire risk of electricity is a very old one indeed, and that as long ago as five years back it was the subject of report to the Phœnix Fire Office upon the matter, that being probably the first official report ever made upon the subject.—*Electrician.*

Local Authorities and Electric Lighting.—At a time when electricity is considered as the power to be used for lighting in the future, and as the local authorities are now called upon to give an opinion as to the conditions under which Provisional Orders of Trade should permit a private company (if at all) to lay cables for supplying both public streets and private houses with electric energy, Mr. Mackenzie Knight has thought that a plain and concise statement of the subject, together with an explanation of the various terms employed by electricians and of some technical details, would be serviceable to the Members of Vestry in their deliberations on this important question. The result is a document of considerable merit even among the very many able contributions on the subject, which have been prepared by the officers connected with the various local Boards of London. In Mr. Knight's opinion it would be highly objectionable to have overhead cables in any street unless these are at a considerable height above the ground—*say* 25 ft.—and as regards the distributing boxes which undertakers are to be at liberty to place in any street during which in their mains are laid, he points out that the boxes or stations might be so situate as to be a serious annoyance to the public economy, and by the frequent opening of such boxes considerable loss might be caused to the traders in the main roads opposite to whose premises they are situate. As regards the time given to private Companies like Edison, Mr. Knight estimates that it would take at least 3l years before the first section could be completed, and 21 years before the total nominal capital of the regulations of the Provisional Order are applied. There are but a few of the many points in this important subject, which are elaborately considered in the Member's surveyor's report.

Electric Lighting on Shipboard.—An illustration of the extent to which the electric light is being adopted on board ocean-going steamers is afforded by the fact that during the past twelve months Messrs. Siemens' representatives have fitted up complete installations on no less than six large vessels, viz., the *Arizona* and *Alaska*, of the Guion line, the *Normannia* of the Compagnie Transatlantique, the *Antonia Lopez*, of the Spanish and Cuban line, the *Antinoë*, of the Peninsular and Oriental line. As this is a year's work of only one agent of one of the numerous firms of companies undertaking this class of business, the *Normannia*, which is not yet quite out of the hands of the fitters, will have 300 lights and the *Arizona* 250, which is completely illuminated by electricity throughout, her equipment including side lights and head lights, engine and boiler room lights, steerage lights, and hold lights. Siemens' dynamos are employed, but the Brush lamp is used in the saloon chance of a stoppage of the light do accommodates are being placed on board, and will be kept constantly charged. The *Arizona* has 300 incandescent lights; the *Antonia Lopez*, 70; the *Orient*, 160 incandescent and 4 arc lamps; and the *Antinoë*, 170 incandescent and 2 arc lamps. The fittings have been specially designed for use on shipboard. The whole of the arrangements have been contrived so that neither thought nor skill shall be needed by those who manipulate them, and so that they can be safely placed in the hands of the stewards and passengers. Even the generators and arc lamps are entrusted to one of the ship's engineers, and some of the installations are superintended by electricians.

1882.

THE METROPOLITAN.

Electric Lighting at St. Denis.—We have been furnished with some particulars of an installation which was completed some little while ago at the works of the Compagnie des Forges et Chantier at St. Denis, and which, though of no special importance as far as the system of the lighting is concerned, is deserving of some attention as being of a decidedly new character. While it was hardly to be intended that electric accumulators have in every respect fulfilled the anticipations of their original inventors, experience has shown that within yet unknown limits they are useful auxiliaries to dynamo-electric generators. These latter can be employed at the direct production of light during the hours of normal requirement, while during the rest of the day they are used to charge the secondary batteries for feeding incandescence lamps when desired. This mode of electric lighting, which enables the highest duty to be obtained from the generators, has hitherto been rather indicated than realised, and for this reason the first industrial application of the method at St. Denis merits special notice. The installation comprises a number of Weston arc lamps and also some Maxim incandescent lamps. The works in question are principally occupied with the construction of railway rolling stock, and the directors of the company desired to utilise to the maximum the power available for obtaining as much lighting power as possible. The engine at the works does not develop more than 80 effective horse-power, of which about 48 are absorbed by the various machines, tools, &c., leaving 32 horse-power free for electric lighting purposes. Under these circumstances it was not possible to maintain more than ten arc lamps, which, however, are being easily by a Weston machine, and the light afforded is exceedingly regular and satisfactory. During four hours each day the Weston generator is employed to charge 80 accumulators of the Kabath company, placed about 250 yards from the generator and connected to it by insulated overhead conductors. These accumulators, arranged in two series of 40 each, are able to supply each day during the period of lighting representative horse-power, the current necessary to feed 30 Maxim incandescence lamps distributed over the painting shops and drying sheds. As this installation has been in operation for nearly two weeks some particulars as to the cost of the lighting are available, and summarising the figures before us, we find that the arrangement, after allowing for depreciation and interest on capital, works out at about 12s. 6d. per day. It must be forgotten, however, that in this case the power is obtained for nothing. The cost of gas to produce the same amount of light, and at the Paris prices, would be about 14s. 9d. a day, or 2s. 3d. per day more. On the question of economy, therefore, there is a considerable balance in favour of electricity, besides which there can be no doubt that the new system is greatly superior as regards security from fire, a matter of very great importance in a factory containing large quantities of inflammable material.

The Electric Lighting Act, 1882. By W. CUNNINGHAM GLEN and ALEX. GLEN, (Knight and Co.)—Messrs. Glen are universally recognised as authorities on the Electric Lighting Act of last Session—a measure of the utmost interest and importance to local authorities throughout this country—is therefore likely to be very generally accepted by such authorities as a sufficient and reliable exposition of an exceedingly complex statute. The full text of the Act is given arranged in a convenient form for the purposes of reference. The authors have also thought it desirable to place some sections of the Tramways Act, 1870, which do not appear to have been entirely superseded. Notes and cross references, together with a few decisions, are inserted where they seem requisite or likely to be useful. Among the notes will be found a code of rules, recommended by the Council of the Society of Telegraph Engineers and Electricians, for constructing and keeping electric lines and other works in such manner as to reduce to a minimum the possibility of risk from fire or shock, and the waste of electric energy; also the explanation for the purpose of measuring electric currents. The Rules of the Board of Trade, also annotated, are appended, and the work concludes with a full and carefully-arranged index.

Anglo-American Brush Electric Light Corporation.—The poll re-opened after the meeting on the 23rd ult., at the Anglo-American Brush Electric Light Corporation's Chambers, 4, Throgmorton-street, Bank, Messrs. Thomas Hoyle, jun., and Frederick Wm. Thomas Hollis, last-seen two and Wm. Lee, the remaining proposers, having declined to act. Mr. G. Hoyle, on behalf of the report of the directors, and the effect of the proposed arrangements, that a committee of shareholders should be appointed to consider and report on the affairs, position, and general condition of the company, and if possible.—And the close of the poll, Sir H. Tyler, M.P. (the Chairman of the company) moved a resolution, adopting the report of the meeting to Monday next for the declaration of the poll and the consideration and concluding the business.—Mr. Lane-Fox seconded the motion, and it was carried.—Mr. J. Boultbee said he stated that it might be interesting to the shareholders to know that the poll showed a large majority in favour of the directors.

HARPER'S WEEKLY. JUNE 24, 1882.

THE MODERN "ATALANTA."

ALTHOUGH ever since the five Atalanta, so fleet-footed that she outstripped the swiftest runners of Boeotia, was transformed into a lion by Jupiter Aphrodite, the name has been given to many models of speed and beauty, it has never been more aptly applied than to the new steam yacht that the Messrs. Stevens of Philadelphia have just built for Mr. JAY GOULD. The keel of this yacht was laid on the 10th of last December, and her builders have promised to deliver her in New York on Saturday of this week, fully finished, complete in every detail, and ready for a pleasure. She will be 185 feet long, and will be principally modelled with over floating in Amelican waters, where beauty of model has more nearly attained perfection than anywhere in the world, but also in producing the strongest vessel of her size afloat in any waters, strength of construction having been considered everything else from the builders. Being one foot longer over all than Mr. DREXEL'S famous, and lately lost steam yacht, this new yacht is the largest in the American fleet, and is well fitted to introduce the Queen of the second the world for which she is intended.

She is to have a draft of 10 feet 6 inches keel over all, 22½ feet long on deck, and 21½ feet 6 inches on the water-line. Her extreme beam is 26 feet 4 inches, and her draught is 12 feet. Her bow, sharp and high, has a "clipper" stem-head, from which rake nominally to her length over all, and give her a peculiarly rapid appearance as she lies at her. Her run is long and handsome, and her clipper stern is surmounted by a light and graceful railing, and is the feature which adds more than any other to the beauty of a yacht in American eyes. From keel to water-line the two sides of the water-ship are lapped at the edges, the strut being laying successively, thereby securing their ends, and are laid flush, bended bottle, and the first bend being also countersunk flush, so that the outer surface is perfectly smooth. The planking is continued uniformly to the stern-post, which terminates in that of a greater height than is usual, and which are surmounted by a heavy rail of solid mahogany. The hull is painted black, sparkled over by the gilded eagle which forms the figure-head, and by the name in gilt letters on her stern.

The yacht is rigged as a three-masted schooner, with standing gaffs and lug sails, and a square-sail yard on the foremast. The fore-mast rises one mode expressly for her, and all her standing rigging is of the best charcoal iron. Her spreaders are of iron, and built as solidly into the hull as the iron deck that it has by possibility be carried away. The formal part of this house is a large many-windowed room known as the Saloon either side of this, adjoining the saloon, are two ladies' lavatories, or dressing-rooms, which are used *en suite*, or can be separated by the latter, and then become de parlor, large and airy, dressing of tapestry hangings; these lavatories are furnished with marble tables, plate-glass mirrors, exquisitely carved toilet-tables, for easy-chairs, and everything that wealth can provide of comfort or luxury. Of these rooms one is upholstered in white silk and the other in blue. Forward of these, on either side of the passage-way, are two more saloon-rooms, or four in all, each of which could, in an emergency, accommodate two gentlemen with comfortable quarters.

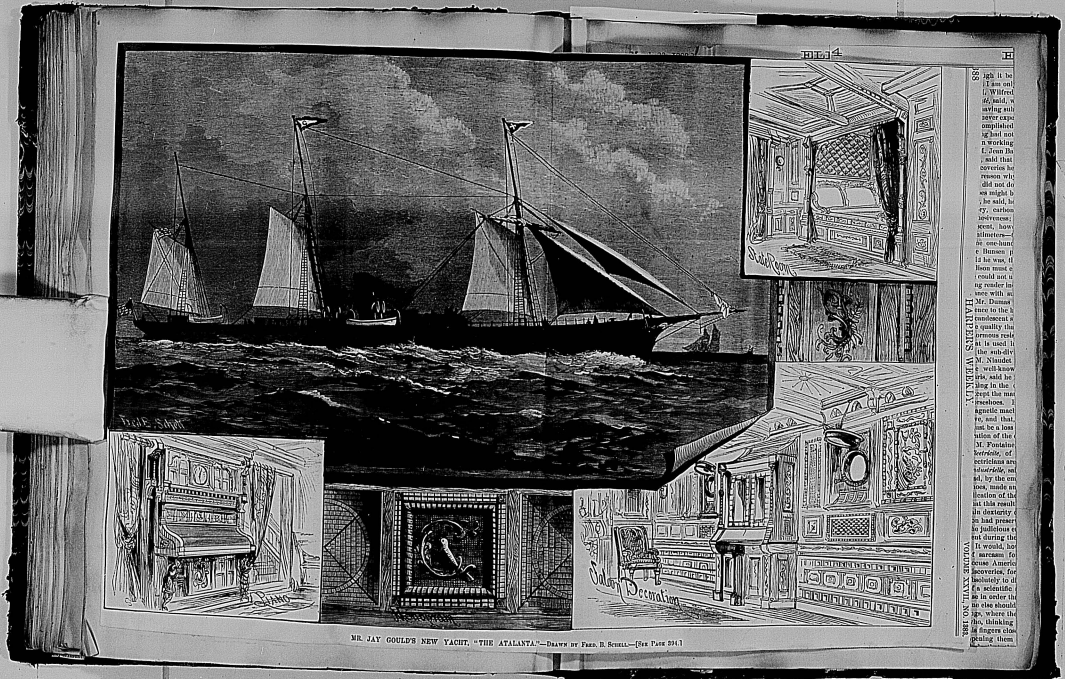
Forward of this is a recess on the right of the passage-way, a long bath-room, or lavatory, fitted up with every luxury. In the collision bulkhead, forward of this are the quarters of the head steward and the six cabin servants, which are reached by a separate companionway from the upper deck.

The Atalanta is to be commanded by Captain STACKPOOLE, formerly of the White Star service, and lately commander of the steam yacht *Minnie*, of the American Line, between Philadelphia and Liverpool. Under him will be two mates, four quartermasters, two boatswains, eighteen seamen, chief engineer, two assistant engineers, three oilers, six firemen, three coal-passers, one steward, three cooks, and six servants, or fifty-two men in all. She is propelled by a compound, horizontal, direct-acting, surface-condensing engine of one diameter brass-power, provided with two cylinders, one thirty inches in diameter, and the other sixty inches. A small engine driven by steam-cylinders of seven inches, which supplies electricity by means of which every passenger may have a light at his state-room desk, and every corridor and final his room with light, to create a motion and measure a current. Every portion of the yacht is lighted with the Edison incandescent lights, and every portion is in direct communication with the engine-room, so that in case of fire or sickness she can be summoned by electricity. By means of a steam ventilating fan the cabins of the American Steam-yacht Co., which is a white Bellows cross on a blue field bordered with red. The cost of the Atalanta has been more than a quarter of a million of dollars.

AUGUST 16, 1883.

THE ARTISAN: NASHVILLE.

The Brush Electric Association of this city, which comprises the southern and Western states for the Brush Electric Light Co., has purchased a recent light gave an exhibition of the incandescent system in the rooms in the Umnite Building, Thursday evening. This is one of the systems of electric lighting which was not represented at the late Railway Exposition held in Chicago. The system has many things to commend it to either large or small consumers. It is considered admirable in their ability to make the light portable by changing a battery that can be moved or placed anywhere. This system, it appears, is just the one for use in a village inside as the cells of stored electricity can be exchanged at each end of a city. It is worthy of an investigation by railway managers.—*St Louis Railway Register.*



MR. JAY GOULD'S NEW YACHT, "THE ATALANTA."—Drawn by Fred. B. Schell.—[See Page 394.]

WALKING seven months of the last twenty, and very perfect in the Scriptures, and their conduct was irreproachable, and their moral character unexceptionable, of considerable intelligence, and of considerable property, and in every way qualified for the work of the Synod.

The decision of the convention is the more remarkable from the fact that the Synod of Kentucky, to which these men belong, is historical. A majority of them, if not all, were ordained by Presbyteries which are known to be in full fellowship with the Southern Confederacy. Certainly, if there is a presumption against any body of men, it is against a body of this character, and yet the convention has taken it for granted that they were loyal men, and has made it a part of the act of admission that they should take the oath to support the Constitution of the United States. Now, if this is not a virtual declaration that the Presbyterian Church in the United States, as represented by the Synod of Kentucky, is loyal to the Government, we do not know what it means. It is a declaration which will be received with great satisfaction by the loyal people of the country, and which will be most unwelcome to the rebels. It is a virtual declaration that the Presbyterian Church in the United States, as represented by the Synod of Kentucky, is loyal to the Government, and that the Presbyterians who have been in the rebel army may return to their homes and their churches, and be received as loyal citizens and members of the Church of Christ. It is a declaration that the Presbyterian Church in the United States, as represented by the Synod of Kentucky, is loyal to the Government, and that the Presbyterian clergymen

HARPER'S WEEKLY.

THE ELECTRIC LIGHT IN HOUSES.

JUNE 24, 1882.

Some years ago the famous Baron Rothschild made a trip in the country, at the time the subject of the invention was unknown, but it is now proposed to have the electric light on behalf of an electric lighting company, to discover how the soft white light of the heavenly star will compare with whether, for instance, the light was supplied from gaseous to the proper color when it is lighted by gas, whether the current could be so equalized that firmness at any point and supply the whole of all points with an equal light, and whether the current could be subdivided so that, as the Baron in his interesting and extensive account of his tour does not know, the same motive, it may be presumed that his solution was a failure, At any rate nothing came of it, and it was reserved for Mr. Edison to evolve without a hearty excessive a method of producing artificially that soft white light which has furnished a theme for so many poets, so that the poets of the future will soon be able to get up a little private room, such for himself, and in spacetopic, even since the heavens without are covered, the silver rays at they come dancing over a basin of water though it is to be devoutly hoped that the same law of peace will not increase with the number of electric lights.

Mr. Edison's invention naturally met with much opposition, and though the opposition has diminished considerably, there are still many who refuse to put faith in the system. They fear that the electric light, like the sword, is revealing, will prove "false and inconstant." The first lot of darkness, who did not believe that Mr. Edison could subdivide the current into small lights, were allowed some time ago by the actual subdivision, and soon the inventor proposes to illustrate to the practicability of his system by illuminating the streets and houses in about a dozen mile of city—that is, about a square. Wall, Nassau, and Nassau streets, and the East River. The island the system has already been tested. Mr. Edison runs a current from what is known as the Pearl-street Station underneath the buildings, supply-ing buildings, Dr. Paxton's Temple, and part of the Post-office, and the result is the Edison Electric Light Company are lighted by Mr. Edison's system.

Yet it is natural that the inventor should meet with considerable opposition. The introduction of gas was at first bitterly opposed; and now that gas is generally in use, in torn spots the introduction of the electric light. How strong that opposition is, may be judged from the enormous power at its back. It is computed that about ten thousand millions of dollars are invested in gas all the world over. Of this amount about three hundred and eighty-five millions are invested in the United States, and about one hundred and five millions in England.

In selecting the down-town district for the first experiment on a large scale in this country, Mr. Edison had in view the fact that the greater the consumption of gas in this district, there is a good deal of steam motor power employed, which the Edison Electric Lighting Company propose to supplies by electric motor power from the same current which supplies the light. A second preliminary success of this district was the following statistics: There are in the district 18,000 gas jets, burning from five and six in the evening; 12 steam-engines, aggregating 3388-horse power; 212 boilers and 20 elevators, and 85 sewing-machines. Besides, the census elicited the interesting fact that the horse-power is used in the lighter manufactories in the evening. Eighty horses were, ever trouble in the big stories of buildings. Some of these horses are kept there all the time they are taken up until they die.

The central station of the down-town district is located at Nos. 255 and 257 Pearl Street. Much work was required before the buildings were ready for the plant. This consists of six dynamos, and the engine-room in the basement of the building is delicately four boilers, with an aggregate capacity of 1000-horse-power, Babcock fittings, two large steam-whistles, steam conveyors for coal and ashes, a fire-proof basement, and the engineering and boiler apparatus. The placing of these requires vaults under the sidewalk, and a trustworthy iron frame-work resting on a strong bed of masonry and cement-work. Each of the six engines has a normal capacity of 125-horse-power, and a maximum capacity of 200-horse-power, making a total maximum capacity of 1200-horse-power. A dynamo is placed in the basement of each building, three tons, so that the weight of the six is 180 tons. The weight of the frame-work and the dynamo apparatus will be about 300,000 pounds, which will be distributed as an average only about 200 pounds per square foot of structure. The boilers, with a total of 1400 horse-power, will consume 100 tons of coal and 4,200,000 gallons of water per annum, or practically a daily consumption of about five tons of coal and 11,500 gallons of water.

A full description of the dynamos belongs to strictly scientific periodicals, and would fail to interest the general reader. Of the machines we can but an expert. They consist in the main of field-magnets energize, between the poles of which an armature or inducing coil is revolved by the use of belting. From the armature the electric current flows through the conductors in the pipes laid in the streets at water flows through a main, and similarly it flows from whatever point the electric current may be required. The supplying or extinguishing of any number of lights in the circuit. A supplementary indicator is shown in the burning of a number of "full lights" in the regulating room.

The laying of the pipes and incidentals proved an interesting and popular feature of the work. The writer remembers how much curiosity was excited early in October last by the queer-looking iron rod boxes that were being piled up on the sidewalks of Gold, Spruce, and William streets. Walking down Spruce Street one afternoon a number of people gathered at the corner of Spruce and William streets having run into a hole. The hole a few feet below the surface was an ample size, and was supplied with man-wrapper. But there was no one to explain the reason of the caliber of the hole or of the box. Soon some curious along and began filling up the hole, but still no information to give. Long before Spruce Street, though, the writer saw that the pipes were being put in on Gold Street. As he approached the spot he now knew similar to that in the hole in Spruce Street piled up. Extra hands on the roadway on either side was dug up a few feet below the surface. A man was talking about in the ditch with a tape measure, and several others were unloading the iron pipes, fitted with the thick pieces of metal projected. When an iron box was lifted into the ditch the writer saw that it was divided into three parts. The middle one contained the pipes which were to be laid in the street, and the two outer pieces of a chair of the city boarded by Sanna, Wall, and Spruce streets, and also East River, and that Mr. Edison, one of the engineers of the company, could explain the purpose.

"Those pipes are ordinary gas pipes which insure their strength," said the engineer, "and the iron box is to protect the pipes lying on the sidewalk—expressed from the cellar to the building entrance. Five kinds of boxes are employed, each in size, and used. They are about a foot long, the inches wide, and one deep. They are respectively junction boxes, coupling boxes, corner boxes, service boxes, and a combination of the coupling and service boxes. The simplest of the boxes is the junction box, in which the connection between two pipes is made. The coupling boxes are set into the sides of curbing, the pieces of metal projecting from either side being connected by the coupling. In the service boxes are connections with the house pipes filled up with a molten insulating fluid, which is poured in through a hole in the top of the box, and closed. The combination coupling and service box is used in the case of a corner house, and requires a third, through which the wires are "served" to the house.

The safety box is an ingenious contrivance to protect the wires from the heat caused by accidental crossing of the wires. The principle on which it works is that when the wires cross they do so accident, the damage caused by the crossing heat is confined to the safety box. In the safety box the fuses of copper wire are interrupted by lead. Although the commencement with the crossing of wires, the heat runs along to the lead and melts it. Then the circuit is broken, and no damage occurred. These boxes are on the corner of every street, in the houses from the sidewalk, and on inspection of these shows whether or not the wires along the line are illuminated. Similarly the junction boxes the lines cross at the corners.

The lamps in the private drive terminate are the Edison incandescent Lamps. Each consists of a glass globe about the size of a large pear, with no to height, exhausted of air, into which is mounted the filament of carbonized bamboo fibre or thus a horse-hair. This filament becomes incandescent when the electric current passes through it, and emits a soft white light. The lamp is fitted into a socket, which is mechanically attached to a chandelier or bracket of a design or to suit the taste of the house. The lamp is simply screwed into the socket, needs no further attention, and, as has been shown, breaks. That is a few seconds it is unscrewed and replaced by a new lamp. The cost of a lamp, besides, is about 80 cents. The cost of the electric light is divided, worked out the question in two different ways. In the former firm, subject to the Boulevard three-cylinder engine, and the coupling it direct to the axis of the dynamos, the supplementary engine-power which may be required. Messrs. Siemens Brothers, on the other hand, considered that in an electric installation, which must necessarily consist of some small, but plenty of itself, was better without the addition of an engine driving direct, and which therefore Mr. Bewsnth, their representative in Manchester, devised a new form of rope transmission, which has been extensively and successful in practice, having been applied in twenty-three instances, among which may be mentioned the steamships City of Rome, City of Paris, Alaska, Arizona, Aumala, Umbria, and Servia. In connection with the space, as the machines and the motors can be arranged very near together and give no trouble in working. It has the further advantage of permitting the use of ordinary engines, either of the vertical or horizontal type, which require no special skill to manage them, and of speeds which do not give rise to tremor or vibration.

A grand electric light-house, having an elevation of 60 meters, is about to be erected at Point de Grave, near St. Antoine-sur-Mer, and will be one of the chief lights on the mouth of the Seine.

At Cannes, on the 4th of April, on the occasion of the International Regatta, there was a grand display of illuminations and electric lights. From 8 to 10 o'clock at night, the boat-sheds of the Mediterranean Nautical Club, the Navarre, the Trident, the Napoleon—the Navarre, the Hendre, and Ocean, the Rallumeurs, the Nautique, the Revenge—and the Lauches Hirondelle, Cygnet, and Hyeres, lit up with their powerful electric lights the City of Cannes, the adjacent islands and the neighboring hills. Immense searchlights, red lights and Mangin projectors were used.

International Electrical Exhibition—Vienna, 1883.

In the course of last month the applications have so much increased that it will not be to follow by continuing our sketch the chronological arrival of the announcements, in order to set on the importance of the Vienna Electrical Exhibition for the progress of electrotechnik in the right light.

We begin with the application of S. Schuckert, at Nurnberg, who, besides a great number of dynamo electric machines for electric lighting and transmitting power, with a great many incandescent lamps and arc lights, will exhibit a telephone machine for coal mines, driven by electricity; the locomotive lamps of the Austrian electro-technical girl, Hermann Sedlaczek, dynamometers, etc. Alexander Kovacs, from St. Petersburg, promises to send a set of his instruments for the department of galvanoplastic, and G. L. Hagen, from the Hague, dynamo-electric machines, instruments for electro-technic measurements, electric lamps and lights, and an electric motor-carriage power, novelties which have hitherto been seen in no exhibition. A. Volsinkel, from Moscow, announces, besides a series of instruments for electric measurements, a dynamo-electric machine for producing differential lamps on a new system, telephone stations, and a new kind of switching and distributing electrical apparatus. The machines to fire mines by electricity, by A. Borsholdt, at Hamburg, will be exhibited in working order. Chimes to fire a mine, manufactured by the Royal Artillery Technical Committee, as well as the Infantry Committee, as well as the Infantry Committee, as well as the Infantry

ELECTRIC LIGHTING MISCELLANEA.

It may be remembered that some time since a great fuss was made about a gigantic dynamo that had been designed and constructed by Mr. J. E. H. Gordon, of the Electrical Construction and Maintenance Company, East Greenwich. As a sequel to this proceeding, it has recently been announced that the Company are prepared to undertake electric lighting contracts, or rather to provide and erect plant on Mr. Gordon's system for corporations and companies. It may be easily understood that the Directors of the Telegraph Construction Company have looked curiously upon the extraordinary rumbling proceeding by new hands to enter in the business of making and selling plant of this description, and have therefore essayed this attempt to utilize their immense works and trained staff in a new department. It may be at once conceded that if electric lighting is ever to be made practically remunerative and commercially profitable, it will be by the intelligently directed endeavours of experienced manufacturing firms like the one under notice, rather than by speculators whose stock-in-trade chiefly consists of patent licences and impudence. This touch appears to have been conceded by the latter class of gentry, if we may believe the statement that the late announcement of the advent of the Telegraph Construction Company in the lighting business has further depressed the prospects of the present electric companies. There is now no doubt that Mr. Gordon is ready to begin operations, for he has published the details of a specification for an installation proposed to be established by his Company for the Corporation of Nottingham. This experimental work involves an initial outlay of about of £220,000 for 60,000 Swan lamps of 20-candle power, or of £280,000 for an alternative scheme of 60,000 1,000 lamps. This is in all respects a workmanlike estimate, and bears the impress of experience in the establishment and working of large manufacturing concerns. The illuminants of the installation may be gathered from the fact that five Gordon dynamos are contemplated, four to be in constant work, and one spare, each requiring about 1500 indicated horse power. Besides this army of power, which is to be obtained from four pairs of the best compound, condensing, horizontal engines of the inverted cylinder type, working with an initial steam pressure of 100 lbs. per square inch, there will be six "small" engines, of 60-horse power each, for driving the exciters. The whole arrangement would be worked for 90 days and nights consecutively by the contractors at their own risk. Mr. Gordon promises that, after all has been done, the light shall cost within 12½ per cent. of the price of gas at 2s. 6d. per thousand cubic feet, or shall return a dividend of exactly 25½ per cent., per annum if charged after the same rate as an equivalent light from gas, estimated by himself. After this, who would not gladly spend a quarter of a million or so, just to prove the correctness, or the reverse, of these estimates?

The Maxim-Weston Electric Company are in sad straits. The shareholders have passed a vote of censure upon the Directors, by not accepting the accounts; and, as a result, an adjourned general meeting has been held, wherein the Board tendered their resignations *en masse*. The next step to be taken will therefore be to elect new Directors, and the meeting has been adjourned for this purpose. All the subscribed capital has gone in various ways chiefly for patent licences), and more is wanted; but the shareholders will not give it, and the friends of the old managers, while still be the end of the difficulty cannot be foretold; but it is almost amusing to read that the former Chairman (Admiral Inglefield) tried to calm the angry proprietary by showing them the gold medal that he had received at the Crystal Palace on the previous Wednesday week for the Company's exhibit of last year. Unfortunately for him, the shareholders would not regard this pretty bit of metal as an equivalent for all the thousands of sovereigns that have disappeared under the Board's management, never to return. It is at least to be regretted that every shareholder could not receive a medal for himself by way of memento of his lost property.

amperes at the outset, falling gradually to 0·3 amperes, or six-tenths of 0·45 amperes. But a current of this intensity requires theoretically the consumption of 11·94 grms. of zinc hourly per element. It is always possible that the actual result may fall short of theory, but here we have a discrepancy exceeding 100 per cent., and it is therefore to be desired that Mr. Trouvé would carefully repeat his experiments, so as to obtain more probably figures. Nevertheless, it may be lost to modify the conclusion which he has believed, it possible to draw in his former remedy."

Bells Unpower Machines.

Editor Electrical Review:

A good invention will survive all adverse comments thereon, and, were it not for several extraordinary misrepresentations in reference to my unipolar dynamo electric machine, I would have allowed all criticism to pass unnoticed.

Objections have been made to the use of the name "unipolar," but not a single sensible reason has been given, why it should not be used. My fundamental invention consists in the employment of a conductor coupled at one end with one pole of a magnet, but I find it an advantage to utilize both poles of a magnet and therefore employ two armatures, one with each pole. The two poles can be on opposite sides of the same disk or drum armatures.

It seems to me that it is far more appropriate to apply the said name to my machine than to that of Siemens and Haiske, in which two copper conductors are coupled at the ends in connection with two magnets, each cylinder revolving between two poles (one of each magnet) of opposite polarity.

I am often results, and cure nothing for names, and if any one can suggest a more appropriate name for my machine I will be pleased to adopt it.

None of my machines have been placed on the market in this country, and only a limited number of machines of the first pattern have been made in Canada. Having the expectation of exploiting, who appreciate the importance of a first-class and complete system of electric lighting and motive power, there has been no necessity for placing an incomplete system on the market in this country.

The criticism of the *Electrical World* on my machine is simply misrepresentation and theoretical blunder, as experience will demonstrate. That the expert of the said paper is a mere theorist and book electrician, is quite evident from his comments on electric lighting, which contain nothing new, being nothing more than a rehash from other writings, and in which I can say from experience will stand any inventor or electrical student, if closely followed. I owe no success to the fact that I have ignored the old theories, in reference to the action of the sing armature and lines of force.

Adverse criticisms upon my machine have, naturally, been expected, for the reason that nearly every electrical writer has become so thoroughly imbued with the old theories, in reference to the action of the ring armature, that it is difficult for them to quickly comprehend a new discovery that is diametrically erroneously been governed by one of Faraday's experiments (1832, par. 1867, in which he employed a rotating copper disk between the two poles of a magnet, and found that when the it rotated over one pole than the other that the effects obtained were by no means so powerful as when it rotated equidistant between the two poles. (Faraday's Experimental Researches, 3197.)

In one of my own experiments, similar to that of Faraday, I found that just the opposite effect was produced in a ring armature, and also that the best effect was produced when one pole was altogether discarded, thereby demonstrating that there is a great difference between the copper disc used by Faraday and the armature of the present day.

Furthermore, I am prepared to disconstrate the importance of my unipolar discovery by making a compositive test with my bipolar or multipolar electric generator in the market.

The New York *Electrician* in referring to my machine says:

"The arrangement shown also involves mechanical difficulties which must prove very serious. It will be observed that by presenting only one pole of the field magnet to each armature, the armature is powerfully attracted toward the pole, and the whole strain of this attraction is brought to bear immediately upon the armature shaft."

The fact that not the least detrimental effect has been experienced with the armature shafts of any of the machines which have been in constant use in Canada for over two years, is sufficient evidence that the above opinion is of no account.

The following misstatement by the same journal:—"Some of the machines with the ordinary bipolar field and a single armature, which are now in common use, show a net efficiency of over 90 per cent."—also needs correction.

The most net efficiency (the proportion of power accountant for in the lamps or external circuit) of the four best high tension machines (Burgin, Gramme, Siemens and Weston) at the late Paris Exhibition is 42.8 per cent.

The net efficiency of my unipolar machines of the first pattern, as tested in England, is 39 per cent., being the highest of all high-tension machines, while my latest improved machines have given results as high as 50 per cent. It is said that Edison claims a net efficiency of 80 per cent. for his dynamo machines, but it must, however, be borne in mind that it is only used for incandescent lighting, and that his copper conductors are coupled in series in a low-tension machine than in one adapted for arc lighting.

The armature of the machine now in London is only 8" in diameter, and consequently will run at a high speed. The revolutions of an armature can be lessened to any desired number by increasing the diameter thereof.

The periphery speed and not the revolution of an armature is the important factor.

Mr. Rankin Kennedy in a communication to the *London Electrical Review* of the 7th ult. says:

"That it can hardly be claimed as a discovery of any kind, as it is well known that one pole of a magnet can generate currents in a rotating Gramme bobbin."

Other writings have also been discovered to claim that I have made no discovery by citing experiments made by Faraday in which he employed a copper disc rotated nearer one pole than another, and also to the experiments in which he employed a copper disc in one pole of a rotating permanent magnet. In both instances very weak currents were, however, generated.

It is quite evident that Mr. Kennedy and other writers have misconstrued the import of the fact that the best results are obtained in a ring armature when it is subjected to only one pole of a magnet.

The electric generator devised by Mr. Kennedy with its employing a ring armature with four pole-pieces as shown in the *London Electrical Review*, of March 17, 1883, fully confirms his ignorance of the said fact, as it is the most unscientific machine that I have invented.

Mr. Kennedy and also the expert of the *Operator and Mail* further show their complete ignorance of the subject, the former by suggesting an electrical wave, in connection with two like poles, which he terms the true unipolar principle, as an answer to my claiming as an anticipation of my invention the carbon regulating mechanism of the arc lamp devised by M. Tchikoleff, a Russian, in 1876, which consists of a ring armature employed as a source of electricity, with four pole-pieces of like polarity, the magnets of which being in two parallel circuits.

It is quite evident that if the said lamp regulating mechanism had suggested the advantages of employing an armature with but one pole, that all inventors would not have been working in ignorance of the said advantages since 1876 by constructing bipolar and multipolar generators.

I cited the experiment of an armature with two like poles about four years ago and discarded the arrangement on account of the unsatisfactory results given.

I will add that in the opinion of present patent experts who have thoroughly examined the matter this alone is novelty in my invention, and that the bread claim of an armature with one pole of a magnet allowed me by the Patent Office.

C. E. BALL.

Triumphant Over All Obstacles.

THE ELECTRIC LIGHT FORCES ITS WAY INTO THE STAID CONNECTICUT CAPITAL.—THE PART THE PRESENT AND THE FUTURE.

HARTFORD, Conn., May 8, 1883.

The unexpected boom that has been given to electric lighting in this city within the last few weeks is attributable to three causes: A long delay since a company was first organized, and through the press and otherwise made very big promises which amounted to naught; a growing feeling of mortification that Connecticut's sole capital should be behind her sister cities of smaller size and less resources in exhibiting herself of this great illuminant, and a general dissatisfaction with the gas furnished by the local company for both public and private lighting purposes. As regards the latter reason the Mayor voiced the public sentiment when in his last message in which he declared that the lighting of the streets of the city has not been satisfactory in any respect.

At any rate, we have got the electric light now, and it has come to stay. It is not simply an experiment even here, for its practical value is fully established, and our streets are now the ceiling for the lamps faster than the company can put them in.

The American Electric and Illuminating Company of Boston have just completed their contract for the 200 lights ordered, and have now contracted for a plant of 100 more to be put in by the latter part of August, or earlier, if possible. Eight years ago the same company put up their first light, and the extraordinary advance they have made since is in spite of the strongest opposition. But perhaps a brief retrospect here would be in order.

The present company was chartered in 1881, just after they got their interior wires laid in more of them until 1882, when they came up again asking for more privileges. Inquiries as to their standing were made, the substance, that they were in no particular hurry, but were waiting for some more capital to be put in. Connecticut like, they were willing to let other cities do the experimenting, and they would reap the benefits of that experience.

It was the opinion of some of the stockholders, too, that simply an arc system would never pay here, and that it was best to wait until some other incandescent light should be devised; but it was coming, oh yes, it was coming; but patient as a few others" Micawbers while the gas company people were laughing in their sleeves. But last fall matters of a different complexion began to take definite shape. Then the stockholders woke up. A meeting was called, considerable stock was taken, and on the following officers elected: Mr. A. G. Dunham, President; Mr. H. H. Starkweather, Vice-President; Mr. Howard M. Clark, Treasurer; Mr. S. G. Dunham, Secretary; Mr. G. L. Hubbell, Superintendent, and before the people were fully aware of it a building for this purpose was up.

The American Company were so thoroughly convinced that the investment was a good paying one that they took out in stock most of the expense of putting in the first plant, and are well represented in the management of the company.

The plant is in every way fully up to the manner in which our people usually do things; consisting of four dynamos with a capacity to feed fifty lamps each, run by two beautiful 50 horse power Armington & Sims engines made expressly for this purpose.

The company made a bold strike in the first place by putting in twenty lamps at the Union depot, where everybody would be most likely to see the light and judge of its merits. Of course the gas company fought this home-shot tooth and nail. They even offered to light the depot for nothing if the electric lamps were kept out. But up they went, and the public came, saw and were conquered. The company have succeeded even beyond their expectation. The leading merchants generally demand the light. The prices here are lower, I believe, than in other cities—it costs a single lamp per night, say 60 cents for two or more; and this is done at a fair profit.

The principal obstacle so far has been in keeping the wires. The street commissioners don't want to give permission to put up poles in the streets. Thus far the wires have been carried over private houses by arrangements with individuals, but the consent of most of them was hard to get, and then only on condition that the wires should remain but temporarily. But the company have established a precedent to assume the responsibility of lighting the streets, which, if accepted, will of course carry with it permission to put up poles. There will be in place 400 gas lamps with 100 electric lamps, and to illuminate the outlying streets with improved naphtha lamps. This will do for a starter, and moreover they agree to furnish lights every night in the year, and every week in the year for $9,000 less annually than the gas company are receiving, for there is a strong public sentiment back of it. Singularly enough no part comes from an unusually wealthy and aristocratic quarter—the Hill—and for a purely selfish reason. The young people out there are particularly devoted to lawn-tennis and croquet parties, largely gotten up by the Trinity College students, and moonlight excursions are arranged. To hold these early in the afternoon is very inbeen in spite of the strongest opposition. But perhaps a brief retrospect here would be in order.

The present company was chartered in 1881, just after they got their interior wires laid in more of them until 1882, when they came up again asking for more privileges. Inquiries as to their standing were made, the substance, that they were in no particular hurry, but were waiting for some more capital to be put in. Connecticut like, they were willing to let other cities do the experimenting, and they would reap the benefits of that experience.

While still be the end of the difficulty cannot be foretold; but it is almost amusing to read that the former Chairman (Admiral Inglefield) tried to calm the angry proprietary by showing them the gold medal that he had received at the Crystal Palace on the previous Wednesday week for the Company's exhibit of last year. Unfortunately for him, the shareholders would not regard this pretty bit of metal as an equivalent for all the thousands of sovereigns that have disappeared under the Board's management, never to return. It is at least to be regretted that every shareholder could not receive a medal for himself by way of memento of his lost property.

[SEPTEMBER 7, 1883.

NEW YORK HERALD.

THE LOUISVILLE EXPOSITION

What It Has Accomplished and What Its Influence Will Be.

A TALK WITH PRESIDENT DU PONT

The Coal Mines and the Art Collection—The Coal Beds by the Lean of Northern Pastures.

Mr. B. Du Pont, President of the Southern Exposition, at Louisville, is in the city, his particular mission being to secure reduced rates to Louisville during the remainder of the Exposition. Yesterday he put the case before Commissioner Clark, and the representatives of the various trunk lines. An agreement was soon whereby half rates during to Louisville will be sold on certain days.

A Herald reporter asked Mr. Du Pont how the managers were pleased with the prospects of the Exposition.

"The managers have every right to be satisfied with the situation," he said, "We expected an large attendance in August; it was to be the month of vacation, but the opening was made a week remarkable to it, and it has been well done. The exhibits are all in place, and the attendance, especially during the past two weeks, has been large. In the course of a week or ten days a number of additional persons visited the grounds. In September and October we expect a large increase."

"What are the distinctive features of your Exposition?"

THE DISPLAY OF SOUTHERN RESOURCES.

"It is an exposition of the resources of the Southern states, and the display of raw products from the field—of grain and grass, of wood and coal and minerals—is unequalled in the country. Our agricultural machinery is second to none, and the mechanical exhibits are very good. Besides all, the city itself invites to the fact that business opportunities are to be found here, and the fact that the Exposition is a success is evidence that the people are alive and willing to supply it. It is the statements of the exhibitors that the Exposition is a success, and it is more interesting to visitors than that of any other in Philadelphia."

"Are you better enabled to light the buildings by electricity?"

"The buildings are very extensive, including, with the corridors, about seven acres under a park, making in all forty-five acres to be lighted. In the Philadelphia Exposition the buildings were not connected, and the lighting was done with the electric arc. The effect is wonderful, and to the art gallery it is particularly fine, but it is not adapted to the use of the Louisville Exposition, for the reason that in the United States gas light, in addition to all this, several times more illuminating power than in Philadelphia, and on the grounds, and no one would be willing to pay for electric lights when gas-lighting is to be had everywhere."

THE ART LOAN COLLECTION.

"The pictures are a magnificent display."

"It is difficult to estimate in pecuniary terms the grand show by this loan collection, for which we owe to Mr. Clark, of New York, and Mr. Corcoran, of Washington, and other gentlemen. Nothing greater can say on Saturday afternoon when the great collection is packed, except the pleasure to get into the building. It is a constant succession of pleasure. The collection is a most valuable one, and the exhibition of it is a most valuable feature of the Exposition; at the kindness of our friends in the East we owe it to the fact that the Exposition is the second occasion of any will be held in the country, and on this account, as well as because of the value of the collection, it is very fine."

"Are you satisfied with the coal beds, which, it was said, when we were in a country and mine, and were found, anything else of interest, Mr. Du Pont?"

"Yes, in every particular, will be the chief benefits derived from this Exposition?"

"The benefits will be answers to the expectations of the managers. The coal beds and the capabilities of the country are known, and beyond all doubt. It is the idea when the people of the North and South will meet socially rather than on business, and the result will be a better feeling between both sections. Louisville is the border land. It is half-way between the North and South, and the people of both sections meet here. The Exposition will be a success for such a reunion, where the people of each section can meet on common ground. The Southern districts was selected for the Exposition, and Louisville as centrally the figuring of the South, and the people of the North and West will come here in the same spirit that they would go to Philadelphia were years ago may be induced to visit Louisville, and the people of the South will go to Philadelphia seven

AUGUST 1, 1883.

NEW YORK DAILY TRIBUNE.

THE SOUTHERN EXPOSITION.

THE OPENING TO TAKE PLACE TO-DAY.

DESCRIPTION OF THE BUILDINGS—ARRIVAL OF THE PRESIDENT.

[BY TELEGRAPH TO THE TRIBUNE.]

LOUISVILLE, Ky., July 31.—Yes, the Southern Exposition will be one of the largest affairs of the kind that have ever been held," said General Manager Wright yesterday. "Our main building has only been extended in order for the principal building for the great London World's Fairs and by the main building of the Centennial Exposition. It is a great deal larger than the main buildings for the Paris and Vienna Expositions. Without counting the space occupied by its annexes, it covers over thirteen acres."

The Exposition building is a handsome structure, light and airy in architecture, and admirably adapted for displaying exhibits of the best advantage. The building is quadrangular in form, and incloses four court-yards, each of which has a large central fountain bordered by tropical plants, and broad tan-bark walks winding through a bright carpet of grass. At night the building will be lighted by 4,000 Edison incandescent electric lights, connected by more than forty miles of copper wire. The park and court-yards will be lighted by the Jenny arc light.

A whole army of busy workers have been scattered through the building, and gayly decorated booths have been erected in all directions. Exhibits of all kinds have been ordered in position. The immense engines for driving the machinery that fills more than one-third of the ground floor have been set up and tested. The great organ is completed, and a rehearsal of the Louisville chorus, consisting of five hundred voices, has been held. During the Exposition, organ recitals will be given by Messrs. Morrison, of New-York; Whiting, of Cincinnati, and Dottier, of Baltimore. Per the first fifty days of the Exposition, Capoul's Seventh Regiment Band will give daily concerts, and for the last fifty days, Gilmore's band will furnish instrumental music.

THE GROUNDS AND THE BUILDINGS.

The grounds of the park in which the Exposition is to be held, comprise eighteen acres, in which there is to be found a fine collection of forest trees. There are a hundred and fifty varieties of trees, flower beds with hundreds of varieties of blooming plants, fountains, summer-houses, mock-castles and rustic monuments. An electric railway makes the circuit of the grounds.

The agricultural department has a particularly interesting exhibition. On grounds south of the main building a small "farm" has been laid out, in which are growing the various species of farm and garden products cultivated in this climate, besides many from other parts. There are large fields devoted to cotton, tobacco, sorghum, flax and sugar-cane.

The art gallery is a handsome fire-proof building in the form of a cross, situated at some distance from the other buildings, in a pretty grove of trees. The walls are of brick covered with cement; the roof is of iron and glass and the floor is of cement. The building is substantially built and will be one of the coolest places in the Exposition grounds. The art display will be exceedingly fine. Among the contributors to the loan exhibition of paintings are August Belmont, George L. Rives, H. V. Newcomb, D. O. Mills, James H. Keene, ex-Governor Cornell, John Hay, W. H. Stevens, John Ogden, J. Pierpont Morgan, and R. G. Dun, of New-York; James L. Claghorn, of Philadelphia, with local contributors (General Sherman will lend seven rare old Gobelin tapestries, General Grant, his large collection of curios and souvenirs; Samuel J. Tilden, the statue of Pluto, from his house in Gramercy Park; Mrs. Potter Palmer, of Chicago, a large collection of bric-a-brac, and many others will contribute pictures, statuary and other works of art. The American Art Union collection of pictures—comprising 153 examples—will occupy an entire wing of the art gallery. The portion of the exhibition will be under the management of Charles M. Kurtz.

ACCOMMODATIONS FOR VISITORS.

Visitors to the Exposition will probably find little lack of accommodation at the numerous hotels here, which promise that their rates will not be increased during the Exposition days. Those who wish to remain in the city for solid time, however, and who would prefer furnished rooms or boarding-houses to hotels, will have poor opportunity for choice accommodation, except at extortionate rates. Rooms that could be rented all winter at from $6 to $8 per week, ordinarily, are now held at from $2 to $3 a day. Many families will vacate their dwellings in the city while the Exposition is in progress, in order to rent the rooms are owned. Of these there are a large number. Few of them are lighted with gas because gas is too expensive, and there is generally a stipulation that the tenant shall not use it. Water is also scarce, and hard rooms are scattered in half of the single-story houses, and water often can only be obtained from hydrants in the back yards, which are shared in common. The rents, as a rule, are exorbitant, and their charges are high, but honestly say that, with an occasional exception, the only rooms about ever to a tempted years, and they intend to make the most of it. Most of them seem to think that the rents will be paid, be obtained after the Exposition is fairly opened.

THE EXHIBITS NOT ALL READY.

All last night and Sunday more than 2,000 men worked without ceasing in the Great Southern Exposition, and exhibit after exhibit sprang into place, beauty and completeness. The displays are not all ready; but the blame is upon exhibitors and not upon the management, which has done all it promised and more, opening the building for the reception of exhibits a week sooner than was originally intended. The goods of many have been in transit, consignment, arriving, and within ten days the display in the Exposition will represent every variety of industry in the South and every prominent manufacturing interest. No laborer will be employed on Sunday hereafter. All national, State, city, military and civic guns will be fired, and the main building, are numerous bands and other features of interest will not be allowed by the management.

The exposition is bound to be a success. The people of the South, reduced as Atlanta is years ago, appreciate to its full value the opportunity, afforded them, and every Northern State is represented by displays of great or less magnitude, while the people promise to come in great throngs to meet their more prosperous brothers of the North.

At 11 o'clock this evening President Arthur and his party attended a reception to Terry Belmont, Governor Blackburn, Governor Carter, Governor Foraker and Presidential party at the Galt House. Visitors attended, among others General and Mrs. Sherman, Mrs. Logan, Mrs. Sheridan, President G. D. Shepherd, of the Louisville and Nashville Railroad; General Harvard and H. H. Green, of Boston. The attendance was large and the entertainment brilliant.

ELECTRICAL REVIEW

A WEEKLY JOURNAL OF

ELECTRIC LIGHT, TELEPHONE, TELEGRAPH AND SCIENTIFIC PROGRESS.

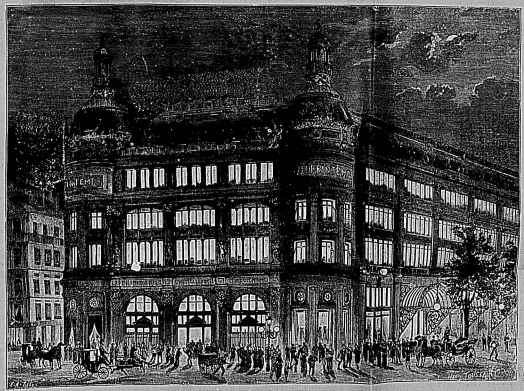
The Electric Light in the Grands Magasins du Printemps.

(Translated for the ELECTRICAL REVIEW *from "La Lumiere Electrique.")*

Thanks to the rapidity displayed in the reconstruction of the great dry goods store called the *Magasins du Printemps*, this vast establishment is now in full activity and the terrible catastrophe of March 9th, 1881, has permitted the replacing of the buildings which occupied nearly one-third of the block on the boulevards on the side of the building on the Rue de Provence, where the gallery was being raised, which terminates in the pavilion at the angle of the Rue Caumartin. These gallery, as well as the pavilion, which is symmetrical with those of the principal front, and will correspond with that which is to be constructed at the fourth angle—between Haussmann and Rue Caumartin—were begun in February last and finished four months afterward.

Our engraving gives a general view of the building, and represents it with all the elevations shown in our engraving, and which terminates the angle of the great quadrilateral of the Boulevard Haussmann and the Rue Caumartin, that can only be begun after several stories, now occupied by merchants with unexpired leases, can be taken possession of, either by expiration of the leases or by accepting the heavy indemnities demanded of the founder.

When this latter portion shall be completed, all the service will be organized on an immense scale, and that, with which we are specially occupied—the electric light—will present a general installation certainly unique in the entire world. We can judge of what the effect will be when it is finished by the one which we already have been accustomed under the numerous difficulties connected in the hasty construction of such a magasin. In fact, up to the present time, the steam engines and dynamo machines have been installed wherever room could be found in the rear of the unfinished basement. Of course, the arrangements are only temporary, but nevertheless, the quantity of light furnished is very considerable, since there are in use 10,000 Jablochkoff candles and 112 Mo-



THE ELECTRIC LIGHT IN THE GRAND MAGASINS DU PRINTEMPS.

bounded by the Rue du Havre, the Boulevard Haussmann, the Rue de Provence and the Rue Caumartin, by a magnificent palace consecrated entirely to Her Majesty, *The Fiakers*.

In July, 1881, the foundations of the principal front, on the Rue du Havre, were commenced, and this portion of the building was far enough advanced in October, 1882, to allow the storing of merchandise. We published in the number of March 25, 1882, of this journal a description of the state of progress of the work at that time, and a perspective view showing the electric light in its fullest activity. The effect produced by this gigantic glass edifice is truly extraordinary, and the whole neighborhood appears as in broad daylight, notwithstanding the effect of this powerful electric illumination. The engraving shows the front on the Boulevard Haussmann, as it will appear when completed. It is not, however, finished, for since the month of April, 1883, the portion which is on a level with the awnings is still occupied by the workmen, and is open to the sky. It will not be until 1884 that the galleries, as well as the grand nave, can be opened. As to the latter portion, which is now shown in our engraving, and which terminates the angle of the great quadrilateral of the Boulevard Haussmann and the Rue Caumartin, that can only be begun after several stories, now occupied by merchants with unexpired leases, can be taken possession of, either by expiration of the leases or by accepting the heavy indemnities demanded of the founder.

When this latter portion shall be completed, all the service will be organized on an immense scale, and that, with which we are specially occupied—the electric light—will present a general installation certainly unique in the entire world. We can judge of what the effect will be when it is finished by the one which we already have been accustomed under the numerous difficulties connected in the hasty construction of such a magasin. In fact, up to the present time, the steam engines and dynamo machines have been installed wherever room could be found in the rear of the unfinished basement. Of course, the arrangements are only temporary, but nevertheless, the quantity of light furnished is very considerable, since there are in use 10,000 Jablochkoff candles and 112 Mo-

dynamos with alternating currents, each one furnishing twenty lights, a combination certainly unexcelled. At the apex of the Mansion lights; on the other side four new alternating-current machines for twenty lights each and Gramme continuous current machines to actuate the numerous incandescent lights.

The supply of steam for the greater part of these motors is furnished by horizontal Belleville boilers; and in the final installation when completed there will be eight of large size and six smaller, which will supply four Creusot engines, developing a total force of 800 horse

THE MONTREAL HERALD AND DAILY COMMERCIAL GAZETTE. APRIL 6, 1883

THE NEW LIGHT.

"Illumination" is the word of the present time. The Electric Lighting event has been the illumination of the Edison Light at the Canada Paint Company's works, at Point St. Charles, on Friday evening, as may be found elsewhere in our columns. Mr. Edison, it may be remarked, if not a Canadian, can claim a relationship with the Province of Ontario, where his parents were born, his mother being of Scotch and his father of Holland Dutch origin. Remembering this, and that Mr. Edison was, as a boy, taken from Port Huron to Michigan Light enterprises, since the discovery of the Canadian petroleum fields, Canadians feel that every portion of the light built by a man born in the Dominion, and, in consequence, every piece of machinery exhibition Tuesday was manufactured in Hamilton, Ontario; and, according to the inventor himself, there were very few specimens of his light in the United States—a proof that there is little, if anything, which is impossible for Canadians to do. The Cornwall light was the first test of this patent and upon this rests a claim which has been operated in Canada; and that their imagination [illegible] [illegible] [illegible]

THE CHICAGO EVENING JOURNAL.

THE ELECTRIC LIGHT.

The Aldermen Protesting Their Constituents from Enjoying Its Benefits.

Description of the Edison Incandescent Light, and of the Apparatus.

No Danger from Its Use—Its Advantages Over Gas—The Companies.

Cost; Etc.

While Chicago is ahead of other cities, or up with the times, in most affairs, in the matter of electric lights it has been contemptuously by small villages. This is not, however, because the advantages of the use of electricity have not been seen and appreciated, nor because our people are in this instance wanting in their usual enterprise, but the blame for the backwardness in the use of this invention is due almost wholly to the tactics of the City Council. Enterprising men have foreseen the future use of electricity in place of gas, and, in fact, several electric companies and put capital into the business, but they are dependent upon the Council for the privilege of using conductors in the streets. The majority of Yankees does not afford to put in bodies and engines and all the apparatus necessary for the lights, merely to have the privilege of using the wires. Gentlemen Still, many of the men are waiting for a company that they can trust to guarantee the electricity for them, have met quite a number of times and individually with the City Council, and have put electric lights into their premises independent of any such company, or else, in co-operation with a few neighbors. Among those are J. V. Farwell, Marshall Field, Edson Keith and D. H. Burnham, who have their lights in private residences. Also Mr. Gurdon H. Paddock, in his residence on Ashland avenue; the Calumet Club, the Academy of Music, the Tribune, the Chicago Opera House, the Grand Pacific Hotel, the Field & Co., National City Insurance Building, McCormick Machine Company, Norton Bros., and Clinton Briggs' Block. The Palmer House is also being placed in the list, and is also being placed in Blavelly's Theater. Mr. Blavelly having fitted up sufficient withs in Field & Co. decided on introducing the light for the benefit of his audiences and the safety of his patrons, and was safer, so far as danger from fire was concerned.

It was also a matter of economy. It was found to be pretty well established that there is no case of those having a surplus of power, that it will be to their profit to put in their machinery, and a large saving over the present prices of gas will be made. These lights are not such great novelties as the streets all in some public buildings,

MARCH 1, 1883.

a height that they can be seen at or be near them? The latter are what are known as the lights, the lights of great intensity and concentrated; it is constantly changing color and is very trying to the eyes. The lights used in the places above mentioned are only of the brightness of ordinary gas jets of the best quality; they are red and steady, being what is known as

THE INCANDESCENT LAMP

(the invention of Edison). An ordinary five-foot gas burner is theoretically equal to about twelve-candle power. The Edison burners are of 16-candle power. The incandescent lamp for families, offices and workshops, and are equal to sixteen-candle power, or a seven-hour burner of the very best quality of gas. While this electric light is somewhat brighter than gas, and of a yellow and soft color, it has other advantages which gas does not possess. It is free from odor, does not give off any perceptible heat, may be used in a closed (in a vacuum bulb) it is not affected by currents of air, and is not liable to set anything on fire. The lamp can be held in any position, so that, with the aid of shades, the whole effect of the light can be turned and concentrated where desired. It can't escape and suffocate one. A lamp may be fastened at the end of a wire of any length, so that it can be carried about, a room and used anywhere, in fresh air or foul, upon ceilings, or in library tables, or in the pocket, under water or above it. The lamp costs about one dollar, and even if it should be broken the outside cover is generally burns like a thread in the fire, and goes harmlessly out. Besides, it is unequaled for domestic and general illumination. It is especially well adapted to the workshop, because the light can be started and stopped instantly, and the entire light on the work, and it is so evenly diffused that the eyes are not tired by it. It has also been carried about

THE EVENING BULLETIN, PROVIDENCE, R. I.

[From the Electrical Review, NEW YORK.]

Questionable Methods of Opposing Electric Light Companies.

NOVEMBER, R. I.

Within a short time in this connection we have had occasion to refer to the methods which the Narragansett Company has prosecuted in securing the passage of ordinances by the City Council of Providence, which would practically drive all competition in electric intelligence out of existence. Without entering into the merits of the case, which we have not sufficiently investigated, the action of the Providence Board of Aldermen in refusing to grant the Thomson-Houston Company the privilege of stringing their wires in the streets of the capital of Rhode Island, seems to us to be a most unwarrantable piece of business. The Thomson-Houston Company has a large plant in operation in that city, and has furnished light to a large number of consumers, who, we have been informed, are entirely satisfied with the service rendered them by the company. Under these circumstances, it would seem that the Board of Aldermen would be justified in granting the company the privilege it asked for, and which has been granted in other cities. The Board of Aldermen, however, refused to grant the request, and, as we have been informed, the reason for their refusal was that they were under the impression that the Thomson-Houston Company proposed to use the streets for the purpose of erecting a telegraph system. This is a mistake, as the company has no such intention, and has never had any such idea in view. The Board of Aldermen, however, refused to grant the petition, and the result is that the people of Providence are deprived of the benefits of electric lighting, which they would have had if the Thomson-Houston Company had been allowed to carry out the plans which they had in view.

EFFECT OF THE GRAHAM TARIFF ON [illegible]

[From the Utica Daily Press, May 5, 1883.]

Mr. Graham, the Democratic member of Congress from the Oneida district, introduced a bill in Congress on Thursday last, the effect of which, if passed, would be to place the duty on [illegible] at 35 per cent. ad valorem. The present duty is 45 per cent. ad valorem. The bill was referred to the Committee on Ways and Means, and will probably remain there for the present session of Congress. Mr. Graham's action in introducing the bill is the result of a petition presented to him by the Oneida Community, of this city, asking for a reduction of the duty on [illegible] from 45 per cent. to 30 per cent. ad valorem. The petitioners claim that the present duty is prohibitory, and that it practically prevents the importation of [illegible] for the reason that the profit on the importation of [illegible] is not sufficient to pay the duty. The petitioners also claim that the duty is a protective duty, and that it is not levied for the purpose of raising revenue. The petitioners claim that the duty is unjust, and that it operates to the disadvantage of the consumer, and to the benefit of the manufacturer. The petitioners also claim that the duty is unjust, because the [illegible] is not manufactured in this country, and that the duty is levied on an article which is not produced in this country. The petitioners also claim that the duty is unjust, because the [illegible] is not manufactured in this country, and that the duty is levied on an article which is not produced in this country.

Very respectfully,

WILLIAM H. HARMAN, President.

It was noted at a shooter exhibition that on the morning after the meeting in Providence, there was a large number of people in the streets of that city, and that the [illegible] of the [illegible] in front of the meeting, which was packed and [illegible] with people, was [illegible] and [illegible] and [illegible] and

THE DISTRIBUTION OF ELECTRICITY.

An important advance in electrical science, as regards the distribution of the electric current, has been effected by Messrs. Gaulard and Gibbs in the secondary generators invented by them; the working of which we recently inspected at the Aquarium Electrical Exhibition. In designing this apparatus, the inventors have outlined the path hitherto traversed by electricians, and have taken a wide and decided departure from ordinary practice. Their predecessors in the field have usually followed Faraday in the manner in which they have simplified and extended. Messrs. Gaulard and Gibbs, however, have gone back for a starting point beyond Faraday to Ampère. Faraday's experiments were based upon the action of agents, or of magnetized iron, before bobbins of insulated copper wire, while Ampère's experiments, which have been practically abandoned of late years, were based on the influence of currents upon bobbins of insulated copper wire. Following up this principle, the Gaulard and Gibbs secondary generators, one after another, on the same circuit, are traversed by the same copper wire, through which circulates an alternating current of small quantity produced by a dynamo, which may be placed at any distance from the secondary generators—even miles away. The current thus produced is not only capable of absolute distribution and transmission in great distances, but is available when so distributed and transmitted for the production (at either or) are or an incandescent light, or motive power. Turning to the apparatus itself, we may observe that it consists, in the first place, of a dynamo-electric machine producing, so alternating current. This current is conducted to the secondary generator, which, in external appearance, resembles four columns about 3ft. high and 8in. in diameter, placed a few inches apart on a masonry stand or table, measuring 3ft. 6in. by 2ft., a similar table being placed on the top of the columns, and carrying a couple of handles and the necessary electrical connections. Each of these columns is composed of a hollow wooden cylinder, upon which is wound, in parallel spirals, placed in layers, a cable formed of a central thick insulated wire having six other fine compound wires also insulated, wound around it. Each of the outside or compound wires is composed of 12 insulated copper wires. The cylinders, or columns, as we have called them, are so connected as to allow the electric current generated or induced on the compound wires by the influence of the movement of the alternating current which traverses the thick central wire, to develop different potentials at will, i.e., the different qualities of current required respectively for incandescent lamps, arc lamps, and motive power. The primary current is made to traverse either the whole or any portion of the number of cylinders by turning a small handle, and by this means the quantities of electric energy can be varied at will by the user to suit his requirements. Another handle or switch is provided by means of which the quantity of current generated can be increased or diminished, and the light obtained thus perfectly regulated. It is a very important point in the system or electrical distribution of which we are treating that a metallic-circuit closed circuit is used to convey the primary current. The circuit is closed because it is never opened for supplying lamps directly, as in all other systems. As danger to life is high tension current can only arise when a circuit is open, it follows that with a metallic-circuit closed circuit no limit need be fixed to the electro-motive source of the current, which, on such a circuit is practically harmless. It is only the currents in lines on the secondary side of the generators that are dangerous to life, and these are, as such as waterfalls, currents and other motors conveyed to great distances without danger, and their power distributed exactly as required.

At a recent private examination of the invention there were two of the secondary generators we have been describing. One of them was supplying a current to 40 Jablochkoff candles, or electric candles, while the other was serving a Jablochkoff arc lamp, five Swan incandescent lamps, and was likewise running a small electro-motor for transmitting power. The latter is the Jablochkoff rellipitic motor, which consists mainly of two coils, the one being fixed and arranged in a vertical plane, and the other being movable and fixed in a horizontal plane, and so arranged as to be capable of resemble that of the ellipse or the cycloid, and hence the name of the motor. The fixed coil is wound on a foundation of copper, and the movable coil on a frame of iron, which, in operation, is transformed into an electro-magnet. With regard to the nominal power of Messrs. Gaulard and Gibbs' secondary generators we may observe that each of those under notice is said to be capable of developing about four horse power, eight incandescent lamps being considered as equal to one horse power. This power can be increased to any required extent, at will, by adding to the number of coil, most of which it will be observed, are in parallel arc. The power is practically applying, and in this respect it is proposed to establish central stations where dynamo machines, driven by water power wherever possible, would be placed. A current would be laid over the district to be supplied, and for each house where the electric current was to be used a transformer would be placed, consisting of a series of 4 cylinders placed a secondary generator. By means of a commutator the current could be put on or taken off the circuit without interfering with the passage of the current. The lamps during working are in connection and the current would be registered by an apparatus in the prime station, which would be a pendulum actuated by the passing current, and this pendulum would turn the hands upon when the charge for the current supplied would be made. It is right to say that the Jablochkoff candles are not yet perfected, far more so than when used from the dynamo last. This stimulates from the circumstance that the electric current obtained on the secondary wires of the secondary generator depends only on the quantity of the primary current, hence the variations of the electric machine do not influence the secondary current. Some of the lamps we saw that night were very fine, and we have brought in question the reduction and distribution of a current sufficient for three old purposes we have indicated above—and that a very important one—namely in practical and then, if indeed, they have not actually solved it their incredible discovery.

FEBRUARY 7, 1883.
DAILY NEWS,

THE LIGHTING OF THE HOUSE OF COMMONS.—The Electric Lighting Incandescent Lamps Bill, as we understand, is to be introduced into the House of Commons, so far as the Committee and passage are concerned, this session. The lamp will not, however, be used for lighting the House of Commons this session, as it is intended to reserve all the requirements of the members and the country of the House. In many of the corridors and rooms of the House, and leading to the conference room, the fan has been, and the library, the gas light has been found rather ineffective, as much so that where flights of stone steps had to be descended, there was a certain danger of stumbling to those who were not familiar with the position of the long series of stone steps by which access is made to the reporters' gallery has been, under the circumstances, considerably lighted. All these defects will, it is expected, be materially remedied by the introduction of the Edison incandescent lamp.

Incandescent Lighting at the Munich Exposition.

(Translated for the REVIEW *from La Lumière Electrique.)*

The Munich Exposition presented a marked difference from the Paris Electrical Exposition, considered from a point of view regarding the application of incandescent lamps. At the latter, the effort made to give the chandeliers and lamp-supports an ornamental character should be pleasing to the eye seemed general, and this applied equally well to arc as to incandescent lamps.

The greater part of the arc lamps were enclosed within elegant lanterns, and the chandeliers with Siemens lamps, which ornamented the rotunda in the exhibition, as also the one with Werdermann lamps in the theatre, and the numerous and varied arrangements for which the latter lamps were well adapted will be remembered. As regards incandescent lamps, the solid mountings of Edison and his out-glass chandeliers may be said to have vied with the elegant blown glass chandeliers of Swan.

At the Munich, however, very little by way of ornamentation was done for arc lamps, all efforts being apparently, directed to incandescent lamps as if it had been assumed that the latter were suitable for domestic uses and that they were the only ones in need of ornamentation.

It appeared also, as regards arc lamps, that the only object sought was to exhibit systems without doing anything in the way of lamp decorations, and we have, therefore, but little to note in this connection except the Compton lamps,—a view of which was given in a previous number—the Schuckert lamp exhibited by Zeltler and Bohm; of Munich, and a drop light chandelier for Schuckert lamps similar to those used by Mr. Jaspar, and exhibited by Mr. Ausmuch, Feuerbermaier and Company.

For incandescent lamps, however, it was quite otherwise, ornamental arrangements being exceedingly numerous and it will readily be seen why this should be so. It is quite a difficult matter to give an artistic aspect to an arc lamp, or to group several of them in such a way as to form an elegant chandelier, while incandescent lamps, owing to their small dimensions, are admirably adapted for the most varied combinations. Incandescent lamps, moreover, can readily be fitted to the supports already in use for gas or candles, and the facility which they possess for burning in any position, renders their installation still more easy. It was thus that the engineers were enabled to arrange in the restaurant garden a most original and picturesque lighting with Swan lamps, these being suspended among the leaves of trees and climbing plants. Being also attached by means of their conducting wires without any show of artifices, and possessing, besides, a certain flexibility, on account of this mode of mounting, they participated in the movements of the leaves, and the garden, as in the story of the "Thousand and One Nights," seemed fairly lighted by the luminous fruit of magical trees.

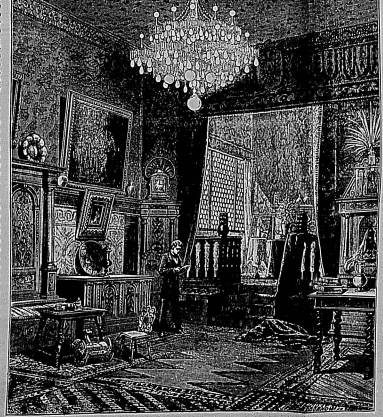

FIG. 1.—SALOON FOR ART TREASURES LIGHTED BY A CHANDELIER OF INCANDESCENT LAMPS.

But this was only an ingenious arrangement showing further the facility with which incandescent lamps can be employed. To return to the apparatus, properly speaking, we will first have to consider the supports and devices for single lamps, and these were found at Munich just as they were at the Exposition of 1881.

Although the subject of considerable attention since that period, they have not changed but remain the same as then; we shall, therefore, not have to reconsider this part of the subject, but will occupy ourselves especially with the more complicated arrangements of electrical chandeliers, in the construction of which the designer's imagination has been given wide scope.

And right here let us be permitted to digress a little with regard to these chandeliers, to protest against the word electrolier, which is beginning to be introduced in electrical language. It comes to us from the English, imitating our word chandelier, they have called every apparatus intended for holding lamps electrolier without perceiving that the latter is introduced in the termination belongs to the root of the word in chandelier, and that to be consistent with this mode of procedure we should call polevtier, polevtier; saurelier, etc. This mongrel word made its appearance about a year ago in the English electrical journals, and since then we have, not without astonishment, seen it repeated in French Journals. Let us take from our neighbors, such as they are, such words as have no equivalent with us, but let us permit them to keep those terms which, though French in appearance, are forged by them contrary to all rule.

Electrical chandeliers were exceedingly numerous in the Munich Crystal Palace. The exposition having been connected with a decorative art exhibition, numerous manufacturers undertook to show that they could do quite as much for electricity as for gas and other methods of lighting; and the result was a multiplicity of different models.

Some of these were nothing more than gas chandeliers slightly modified to suit the circumstances, while others were specially designed for electric lamps; but what particularly struck the beholder was that nearly

THE MORNING NEWS, TUESDAY, APRIL 10, 1883.

HAWELY'S ELECTRIC LIGHT.

Edison's Incandescent System Tested—Minute Description of the Apparatus.

A successful private exhibition of the Edison incandescent light, just introduced into Harrisburg, Pa., took place, was given yesterday afternoon, under the direction of Mr. P. D. Johnston, engineer for the Western Edison Light company, Mr. Edson Sturges, president of the Western Telephone companies; and Mr. Jacobs, general manager of the Wisconsin Edison company, and representatives of the dramatic and newspaper professions were present. The praise of the gentlemen familiar with electrical matters was lavish. The actors present were particularly pleased with the steadiness of light, for the reason that the light given from the lamps was clear, and the unpleasant sputter of the arc light was abbreviated. The effect of the light on the stage and in the vestibules and auditorium, was delightful.

The electric power is supplied by one Lawrence engine of nineteen horse power, driving two sources of electricity known as the "A" and "B" machines, giving 250 lightsaccd, and one "C" dynamo, giving sixty lights. Of the former, one is used to supply the lights for the stage, the other for the auditorium, and the latter for the halls and vestibule. The total number of lights in the theater is 507. In the basement are the dynamo machines, which are used to regulate the candle-power of the separate lamps and give the engineer control over the entire system of lights used, enabling him to maintain the normal candle-power. Connected with the dynamo machines are the wires which carry the current to the stage, from thence being distributed to the boxes, halls of the house. In connection with the wires in the boxes is an indicator, which shows at once the candle-power of the lamp in use. Should the candle-power become excessive it used to show to the engineer instantly where the trouble was, and operating at once to adjust the proper lamp to the indicator. In a bell and two lamps, one in the box office, the other in the dressing room, which are used to regulate the candle-power; above the latter, the call bell for the stage is placed, enabling the call boy to ring violently, notifying the engineer that the current is too low, whereupon he will step over or more and the lamps below assent, the latter lamp is brought into circuit, and the proper high voltage secured, the power is then normal the lamps are cut out and the half over gently turned on.

The "rigs" or "borders" used on the stage are several from the rigging loft, in the same manner as gas fixtures are hung, and are composed of slender metal tubes, in which are placed the wires, scarcely larger than a knitting needle, in this manner the fitting can be moved at pleasure at will. There are five borders, two in front of the proscenium, one in the center of the footlights, numbering fifty, are placed in the same position as the gas lights. The bunch of colored lights, used for illuminating special parts of our scene, are controlled by a switch, and can be moved to any part of it, no matter where the rigging.

The ventilating apparatus for the stage and auditorium light is a fan, placed in the basement, 8 feet wide, 3 within a space two feet deep, four feet wide, and four feet high, are in use. The fan is driven by a four inch belt, and the apparatus can be used for the auditorium, one compartment for the stage, and the other for the ventilation of the dressing rooms, and if we, the engineer, should be unable to control the system of stage lights is furnished as required, and the engineer has the perfect regulating apparatus at his command. The lights in the house can be turned from its most brilliant condition, or will fade out slow or put entirely out at once, and as the light passes from bright to dim, the color shadings are obtained.

The auditorium lights are covered by delicately tinted ground glass shades. Placed in the ceiling, which is arched and ivory panels are studded with silvered knobs, from which, in delicate tones of pink and green, light is given, creating a fine effect. The central chandelier, hung from the dome, has been made especially for the house, at a cost of $500. A temporary chandelier has been hung from the floor, being placed temporarily for the exhibition. The chandelier is of steel and black. It is a beautiful affair, consisting of twelve lamps in varied colors, producing a blush of rose, and gives a beautiful effect to the scene.

The visitors to the exhibition were favored with a complete exposition of the workings of the system, and the engineer, Mr. Jacobs, was kept very busy. Should any accident occur to the system the system of wires has been so arranged that it does not interfere at all with the gas, which can be utilized at any moment. Only two men are required to run the machinery, as employed the electric lights of the Globe theater of Boston, and Daly's Academy of Music, Chicago—but they are as complete as the system at Hawely's.

ELECTRIC LIGHT.

ITS INTRODUCTION AT HAWELY'S OPERA HOUSE.

At half-past 2 o'clock yesterday afternoon an exhibition of the new Edison electric light was given in Hawely's Theater. For some months past the Western Edison Light Company has been perfecting the latest and prettiest of the first exhibition was given to-day. Mr. Hawely, Mr. Johnston, Mr. Jacobs, Mr. Sturges, Mr. Johnston. There were present: Mr. Hawely, Manager John G. Daff, and members of his company, Treasurer Hall, Mr. Hawely, and members of the press. There are in the theatre 67 lights in all, operated by twenty-one lamps—one for the footlights, two for the scenes, one for the stage, and twenty-four for the chandeliers, above the parquet, with 16 candle power each, and twenty-four, also 16 candle power, in the fifteen globes. There are also 16 lights in the vestibule. There are four sets of border lights, each set containing fifty globes, and each globe has sixteen candle power. There are five sets of border lights in the flies, each containing fifty globes, and each globe has sixteen candle power. The chandelier in the center of the parquet has 100 globes, each containing sixteen candle power. There are also 100 globes distributed in the parquet circle, and 100 in the gallery and entrance hall; one hundred and twenty-four lights in the dressing-rooms and stage are also of sixteen candle power.

The footlights in front is the new regular, built expressly for the stage, with 50 candle power, which illuminate the scenes with its many colored globes. The scenes used throughout the house, in the first night's performance of "Pinafore," were manufactured for the purpose of showing the lights. By means of these the lights in any part of the house can be turned on, raised, or entirely extinguished. The lights in the dressing rooms are independent and can be turned on or off at will. The electric lights are to be used in the dressing-rooms, and if we, the engineer, should be unable to control the system of stage lights is furnished as required, and the engineer has the perfect regulating apparatus at his command. The lights in the house can be turned from its most brilliant condition, or will fade out slow or put entirely out at once, and as the light passes from bright to dim, the color shadings are obtained.

Heart and Hand at Hawely's Theatre.

A very large audience witnessed the performance of Lecocq's opera of "Heart and Hand" at Hawely's Theatre last night. It is certainly better put upon the stage than any piece seen in this city for some time. The representations is well worth seeing, and is sure to be thoroughly enjoyed. Miss Lee-Cook, however, is suffering from a severe cold, and her voice is not in the best condition for singing. Nothing marred the performance, however, and the audience was kept in a constant state of laughter. The scenery was unusually fine, the stage was illuminated throughout by the electric light, and the great solidarities of many and varied colors of the sunbeam when the light was turned on, and the effect was perfectly steady, and under such much more brilliant than gas, more contrast. There was no heat from the lights, and its introduction is an important step in advance. The arrangements for this theatre. The scenery and costumes are also illuminated by the electric light, and in the second act the effect of the colored glows was so pleasing as to win another round of applause. Soon, a garlands of sun was used, and when, and even the audience were disposed with toward the close of the performance.

Electric Light Applied to Special Purposes.

Outside of the ordinary illuminating purposes, electric light furnishes the means of attaining certain effects which could not be attained by the ordinary sources of light.

For instance, the projection of a powerful jet of light on a given point which is to be brightly illuminated at a distance could not

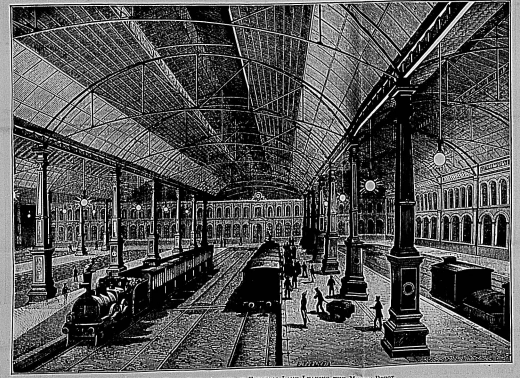

FIG. 101.—TRAIN LIGHTED WITH AN ELECTRIC LAMP LEAVING THE MUNICH DEPOT.

have been easily resolved with oil or petroleum.

Such result, with those means of lighting cannot be merely obtained except by the use of heavy and cumbrous apparatuses only applicable to stationary focuses, such as lighthouses.

For movable projectors electric light alone can be used.

It will not be necessary for our present purpose to refer to the similar appearances of that kind which are used in naval and military applications.

They were represented at Munich only by a very simple modeles of rather large size, which was used within the interior of the Crystal Palace, to produce certain effects of intense illumination.

A much more important machine containing new features was the illuminating carriage of Messrs. G. Schuckert and Meichlaler & Co. For a great number of cases it is very useful to have the power of bringing to a given point all the materials necessary to electric lighting engineered in such a manner that the lighting apparatus may be set up within a very short time.

The support of that lamp, or illuminating tower, is composed of four sets of such Nurnbergish Bleam, combined and worked together, as shown by Figure 97.

That apparatus is folded down on the car rings for transportation.

The folding and unfolding (erecting and raising) is obtained by winching or removing his base by moving to and fro and along the four grooves on the top of the truck the four resting points which form the base of the folding. Such moving is obtained by means of a screw worked by a gear and crank.

The lamp is suspended in the upper part of the tower by means of cords passing over pulleys. When the winching is folded the lamp sets down in a cylindric support or pocket placed in the center of the carriage, to keep it fast in its place during transportation.

The carriage further bears four vertical screws, which can be used to wedge up the machinery very firmly.

The apparatus was exhibited outside of the Crystal Palace, not far from the entrance of the Exhibition, and during several evenings is was worked before the public in order to demonstrate the regularity of the work and the facity of the lamp.

It has also been demonstrated that the raising of the lighting tower does not require more than five minutes.

In order to more fully try the apparatus under that point of view, on the 18th day of October it was transported to one of the squares of the city; wherein it was installed, and twenty minutes after the arrival of the two carriages the engine was under way, the tower raised, and the lighting in full operation.

In spite of the heavy rain, the light given the apparatus was sufficient to read a newspaper at a distance of fifty yards.

ELECTRIC LIGHTING.

TO THE EDITOR OF THE TIMES.

SIR,—You have recently given prominence to an elaborate exposition by a "correspondent" at what is known here as "Mr. Moulton's Provisional Order." Since then you have published a letter from a firm of solicitors on behalf of their clients the "Metropolitan Brush Electric Lighting Company," and from another firm of solicitors representing one of the district boards of works in London.

Although it is not altogether convenient that the professional advisers of contending parties should be publishing through The Times their views on behalf of their respective clients, yet the present subject is one of even more than metropolitan interest, and you will perhaps permit one legally employed professionally in these matters to place before you his views on portions of the recent correspondence.

Confining my observations to metropolitan local authorities, it is notorious that having long smarted under the tyranny of the gas companies they were prepared to welcome and encourage the introduction of electric light, partly on its own merits, and partly as tending to stimulate the gas companies or mitigate their charges. When the Act of last Session was under consideration a few individuals interested in electric light having the avowed support of the Board of Trade succeeded practically in modelling the form of the Act, the local authorities not (in my opinion) having conducted their case to the best advantage. On provisions of the Act (the consequences of which were not probably foreseen by Parliament) empowering any company from making an application to the Board of Trade for a provisional order this Session unless they had entered notice upon the local authority of the district which they sought to supply within one month after the passing of the Act. I believe that period expired before the Act was printed, and the knowledge of the provision was, therefore, confined to those enterprising individuals (representing few in number) who took part in the Parliamentary proceedings on behalf of the electric lighting companies. I find that in more cases than one, notices were distributed broadcast during that month to various local authorities by certain persons, who thus monopolised the entire benefit of the Act for this present Session; and in some cases notices were sent in anticipation on behalf of districts who were yet to come into existence, and the ground was thus occupied. It is important, therefore, in order to understand the true position to remember that there can be no applications for provisional orders this Session except by the initiated few who understood the contents of the Act of last year before it was issued.

When the provisional orders for this Session were drawn and the intentions of the applicants were disclosed or canvassed by the ingenious draftsman prepared by Mr. Moulton. This form has been adopted by the Edison Company, the Swan Company, and the Brush Company, all apparently "in the same swim."

In one order metropolitan case a less transparently delusive form has been adopted and there are not, on the face of it, the same objections; but there is enough in Mr. Moulton's order to justify the local authorities in objecting altogether to its application to their districts. The strongest objections seem to be the following:—

One of the most important matters for consideration is the price to be paid by the consumer for the commodity supplied. In the case of the electric lighting companies confine themselves to providing electrical lines and apparatus for those who desire to use them the price will depend upon the ordinary laws of supply and demand and be governed by competition, and the real or nominal capital of any of the companies in no way concerns the public; but directly the companies seek statutory powers it becomes essential to investigate these matters.

The Metropolitan Brush Company, for instance, are applicants for about 25 different orders affecting the metropolis. Judging from the recent discussions between the shareholders and directors and from what information can be generally obtained, the available resources of that company are at best entirely insufficient to enable them to fulfil the obligations which they undertake, or indeed to provide in all the various districts which they invade even one experimental installation. The nominal capital of the company is one million. The orders contain no provisions for defining or fixing the amount, and it is capable of indefinite expansion by the mere action of the company itself. That somewhere among the existing electric lighting companies there exists already a great inflation of capital, due to the random purchase of patent rights of inconvenience, which may or may not be valuable, and to the process of gambling which has been conducted before the public eye, is strongly suspected by local authorities; and it is now proposed that whole districts in London should be charged in perpetuity in order to pay dividend on this capital.

It is impossible to see on what amount of nominal capital the consumers would have to provide dividend, nor is there any security that this capital shall bear even a reasonable proportion to the cost of the work.

Time does not admit of my discussing this form of order in detail, but it may be broadly stated that it is a specious document, conferring in effect upon the undertakers a very large amount of obligation, accompanied by the greatest facilities for escaping from those obligations, and enabling them to sell in one or more lots the privileges which it will confer. Such a power is so obviously objectionable, that it has been so generally condemned by Parliament in analogous cases, that its insertion appears somewhat indiscreet on the part of the electric lighting companies. The clauses may be explained or withdrawn by the undertakers, modified or refused by the Board of Trade or Parliament, but they have provoked a reasonable suspicion among the local authorities which will be allayed with difficulty.

At the present moment the London local authorities have sufficient power to contract with any body of persons for public lighting, and with very little difficulty they could arrange for private lighting also. They are free to contract to whatever company or system can from time to time provide lighting most efficiently and economically, and there can be no possible reason why, in the present state of electrical knowledge, the best interests of the public should be handed over in perpetuity to anyone particular person or company happening to have got a start this present Session, as is the intention of all others. The applicants this Session are all the representatives of some patent rights or other, and if they should obtain the powers they seek the result will be either that in some cases they can be bought off, or that the consumers will be unduly charged in order to pay a dividend, not only on the capital necessary for the installation, but on that which has been created by the translation of existing rights into paper shares.

If these are the objections which the solicitors of the Metropolitan Brush Company regard as "frivolous," I do not agree with them. They are not by any means the only ones.

May we Londoners not say to the various applicants, "If your patents are of legal validity and practical use and have been acquired by purchase on fair terms, no single person is entitled to you without your having statutory powers, but if their value be doubtful and your expectations upon them extravagant, you must not expect to set those powers right by forcing us to provide you a return on your last expenditure."

A leading director of these companies says to me, "Why make this fuss about our capital and expenditure in patents? You go to Lloyds and Bennett for a bit without investigating their rent, salaries, and income, and do not seek to see the books. Instead of 25s. because they regard those items as too large."

I answer, "True; but if Lloyds and Bennett and two or three others should go for a huge speculation—buy, as my battery, all the existing leases and rights to make use of the recognised patterns, and then ask statutory powers to supply the bats of the metropolis for some 21 years, might we not try to guard ourselves against being during that period let by Pitt, a piece instead of Pic, (without bats and balls!)?"

Then it is urged that these orders will not confer "exclusive" powers. The same was said years ago, when gas and water companies first sought statutory powers, and it is theoretically true of their powers. But the present Draft Orders seek powers just as practically exclusive as those of the gas and water companies, no one can any electric light company, subjected to statutory conditions of supply, be fairly expected to risk its capital on other terms.

Although several of the principal local authorities in London have been represented by speaking—and following—my advice, I forbear to indicate my clients or publish my name.

Yours faithfully,

Parliament-street, M. L. C.

Summary of the Munich Electrical Exhibition.

(*Translated for the* REVIEW *from* La Lumière Electrique.)

We have delayed giving until now any detailed account of the Munich Electrical Exhibition, not desiring to begin until we could obtain all the documents relative to this new manifestation of electrical progress and such data as might be necessary to enable us to make the description as complete as possible.

If the exposition has not proved of as great importance as the one at Paris, it has at least presented many interesting features. Its remarkable organization for electrical measurement and the exhibit of machines and lamps wholly of German make, and but little known in France, have given special interest to the exhibition and added to the importance which it has already acquired in the scientific world with the memorable experiments of M. Marcel Deprez.

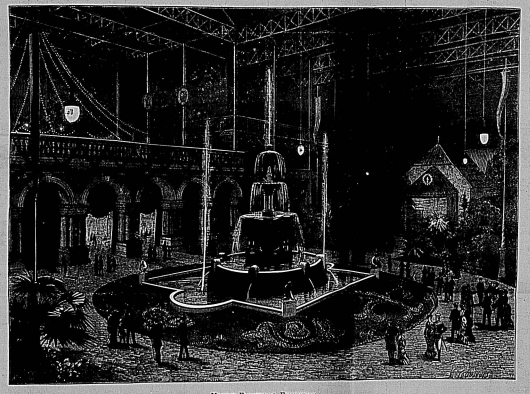
The principal object of the Munich Exposition was to study the practicability of electro-technical application, to make the necessary measurements for a just appreciation of the value of these applications and, at the same time to judge critically of electric lighting from an artistic standpoint.

From the latter point of view a more appropriate place could not be found, for, aside from Paris, where all nationalities seem to meet and devote their talent, the Munich school occupies a foremost rank both as regards the number and talent of its painters and sculptors.

At the Industrial Palace during the Paris Electrical Exposition in 1881 artistic applications of the new methods of illumination were quite limited.

The saloon for paintings, lighted with the Pateil lamp, certainly produced a very happy effect, and the arrangement of the theatre and the apartments of the President of the Republic showed that marvels might be accomplished in the way of luxurious lighting, but, up to this time any lighting of museums and monuments had not been accomplished, while at Munich attempts of the kind were made with considerable success. All who visited the Bavarian capital at this period will recall the excellent effects produced by the Schubert lamps on the Praxenhöfstrasse and at the same time, the electrical arrangements in certain streets. They will also recall the tasteful decorations of the various saloons filled with objects of art, and in which the light from elegant chandeliers illuminated in such a magnificent manner the superb products of Bavarian art.

It will therefore be seen what an amount of interest the inhabitants of Munich ought to take in the study of electrical machines and motors, and above all, in the study of the transportation of force; and it will readily be understood why the Committee on Organization on learning of the statements advanced by M. Marcel Deprez relative to the transport of at a distance, urged that gentleman to give experimental proof of the same, and freely placed at his disposal every means for the com-



MUNICH ELECTRICAL EXHIBITION.

From another point of view the application proper of electro-technics, the place was most favorable; for, if in some cases, where with steam as a motive force, are susceptible of rendering important service, they must be still more serviceable when natural and less expensive forces can be made available.

Now, Munich is traversed by the Isar, whose magnificent falls are capable of producing thousands of horse-power. The natural force thus created is moreover not confined to a single point, for arms of the river traverse thickly in various places, so that the utilized force has there already received a natural distributional beginning.

pete demonstration of his lately experiment.

Notwithstanding these favorable conditions, however, electrical industries were, until recently, but little known at Munich; but when Prof. von Bezold, of the Polytechnic Union, and Engineer Oscar von Miller, of the Society of Architects and Engineers, described before large meetings the marvels of the Paris Exposition, there was no longer among the members of the society but a single desire—that of taking up the study of these new inventions, which were being made so rapidly that the electrician himself could scarcely follow them, and determining for themselves by means of practical experiments their scientific and commercial importance

THE TIMES, TUESDAY, FEBRUARY 6, 1883.

ELECTRIC LIGHTING.

TO THE EDITOR OF THE TIMES.

SIR,—While studiously avoiding the discussion of the details of the Provisional Orders which are now *sub judice*, it seems desirable that we should submit for the consideration of your readers who are taking so keen an interest in the correspondence, the following general remarks from the undertakers' point of view :—

1. The Provisional Orders were issued without aid or guidance from the Board of Trade or other public or private source, without precedent of any kind a new piece of legislation, had to be compiled, comprising difficult scientific and practical as well as legal considerations. The task was undertaken with a *bona fide* desire to grapple with the difficulties, and an endeavour fairly to meet the just requirements of the public, and at the same time to afford adequate protection to the undertakers. It was known that the scheme proposed would be subjected to keen criticism, and be corrected wherein it was imperfect ; but it was not expected that we should derive the advantage of a full public discussion of our proposals. In the result, we have no doubt the Orders will benefit by many of the suggestions made in *The Times*, and it will, we think, be found that the undertakers are indisposed to disregard any reasonable objections ; and, as the last, severity for the most ideal commercial working of the new undertakings, it will be their wish to work hand-in-hand with, and to meet the views of the local authorities, as far as is compatible with a due regard to the novelty of the undertaking, and the yet unproved practicability as regards incandescent lighting, in the absence of the complete perfection of a system of storage, of supplying private consumers on an unlimited scale. That on the profits will depend upon the number of consumers so undue pressure need be applied to force the undertakers to what their first interests will dictate.

2. Your correspondents for the most part represent their own isolated views, and may be excused for not looking at the matter as a whole. It has been our duty to study the subject carefully, both from a legal and commercial standpoint, and we have had to listen to the views of scientific men, of learned counsel, of engineers, of commercial men, and to adjust our views with due regard to many considerations ; and although we believe there is a great future for the electric light, we are impressed with the thousand-and-one difficulties that have yet to be surmounted. Thus the Orders are considered by Parliament the work will have only commenced ; but during the progress of the Orders, the opinion of capitalists will be formed as to the paying prospects of the ventures, investors will be apt to exaggerate the risks, and in view of the present depression in electric lighting shares they will be sceptical as to the profits. Therefore we say, let the public who want the electric light not reckon without their host, but rely upon the enormous amount of capital required being forthcoming unless there is encouragement in given and reasonable protection afforded, and a tangible prospect of profit given. This is plain speaking, but it is better to end the discussion of minor matters not to lose sight of the great factor—capital.

3. Why have the local authorities with but few exceptions not availed of their preferential rights to become undertakers themselves ? In the autumn there was a general disposition to do so, but other counsels prevailed. The report of the Birmingham Corporation Committee pointed out with unanswerable effect the dangers ahead, and showed that for local authorities to enter upon the business in its experimental stage, when experienced undertakers were ready to meet the requirements of the public, would be unwise. The debt being thus upon our clients and others stepped in, and it is to be hoped that the broadest of reasons which prevented the authorities applying may be extended to the private undertakers, and that undue influence may not be attached to the opinions of those counsellors who, now that the companies are applying, would have the authorities comfort as inapplicable to others what applied to themselves, and affect to-day to underrate the risks which yesterday they thought prohibitive, and magnify the prospects of profit they thought unfeasible. Far from the companies wishing to keep the authorities out it was their wish at once to see them become undertakers, knowing that recourse must be had to experienced companies to execute the powers ; but the indirect effect of the opposition to nothing not to cause any misgivings as to the security of the companies rushing in where corporations feared to tread, and thereby with a courage worthy of encouragement, the companies came forward ; and whether they are successful in advancing their own interests and those of the public will be determined by the shape of the Orders.

4. The Orders have been drawn in form to proper account the interest now assumed (from a small scale) as one of the first importance to give weight to the opinions expressed by the numerous critics of the Orders when obtained ; but we do not let any verbal critic suppose that by the phrase, "a reasonable time," a reasonable commodity is made the rhetorical remark as a protest against such a method of legislation, which we should be kept as a higher level. Say it, be it remembered that the best chance of the public securing at an early date the benefits of electric light is through the medium of companies, with the spur of profit to capital, and having an experienced staff, and the chance of carrying out the provisions of the Act, which, by the way, says that no special form of lamp shall be prescribed ; but that the undertakers shall, subject to the companies meeting the conditions, be free, are willing to submit to such reasonable tests as may be considered necessary, the systems are sound and satisfactory, and that "slighted policy of the public" loses the opportunity now presented to secure the early fruits of those attractions of an electric supply, the limit of which cannot be defined !

5. Then, as to the question of monopoly, even the contests before the Electric Light Committee of last Session, as to the period after the expiration of which the undertakers might be compelled to sell to the local authority, and that it was ultimately settled at 21 years, proves that the companies admitted that this was reasonable, and that the period within which the undertakers could keep after securing their undertakings (subject to many limitations that portion of their profits not refunded in the event of purchase. The fears on which the Orders are based are, we think, groundless ; we have the local authority with but partial exceptions, and the Electric Lighting and Power Company (Limited), which, almost alone, represents the Metropolitan Electric Supply Association. Indeed, with which it has been considered, are interested in supplying the public, and in securing to the public capital necessary for the undertakings, and will either prove : as the extent that they are possessed of the requisite capital for the undertakings, or by the powers they will submit that such powers shall remain in abeyance until the Orders have been tested for a term of years as to the success of isolated undertakings, not doubt that any powers should for an undue length of time remain in their hands unexercised.

We are, Sir, your faithful,

WALTER H. ELLIS and CO.

25, Queen Victoria-street, E.C., Feb. 3.

TO THE EDITOR OF THE TIMES.

SIR,—Will you permit me to state that the manager of the Metropolitan (Brush) Electric Light and Power Company (Limited) has expressed his intention to write to *The Times* to-day ? I may perhaps be pardoned for not quite agreeing in understanding the degree of relationship existing between the various members of the "Brush" family of companies.

May I, in my turn, criticise the opening statement of his letter, that he "forbears as hitherto to anticipate in *The Times* the discussion of his draft Order, which is reserved for a another place ?" He must not put on me the responsibility for this anticipation ; as, but for the publication of letters from his company's solicitors, you would not have been troubled with my letter of the 3d instant. They introduced through *The Times* on the 24th of January last the "views" of the London local authorities, who (apparently alone) had not objected to their Order ; and in my former letter, published on the 31st, they broadly characterised the objections of other London local authorities as "comparatively trivial as far as trouble."

Apart from any question between the companies and the local authorities it may be of interest to state that there are 34 applications for Provisional Orders (the Saxton affecting the metropolis—One, by the Edison Company, covering a large central district ; 23 by the Brush Company, covering substantially all London and some suburbs ; three by the Pilsen Joel Company, covering the City of London, St. Pancras, Holborn, and St. Giles's four by the Swan Company, covering the Rosemary square, South Kensington, Strand, and Victoria districts ; and one by the Varley of the parish of St. Pancras ; but with the sole exception of the last-named Order all the applications emanate not from persons desirous of being supplied with light, but from persons desirous of obtaining the right to supply them.

I would like to add, in justice to these new electric light companies, and their able advisers (whatever may be the result of the present applications), that their efforts to grapple with a very difficult problem and to enlighten us upon a subject upon which we are much in the dark, even though not wholly disinterested, will do a great public service and be widely appreciated.

Yours faithfully,

Parliament-street, Feb. 5. H. L. C.

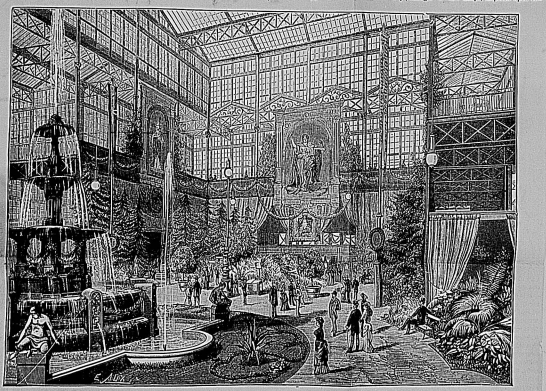
Interesting Features of the Munich Exhibition.

Last year, when the Exhibition of Electricity opened at the Munich Crystal Palace, it will be remembered, a great many electricians, in France as well as abroad, did not believe that it would ever attain anything like the importance it was destined to have. Indeed, in spite of the celebrated experiments which Mr. Jaspard Dupret had begun, and the result of which was expected by everybody, it could not *a priori* be believed possible that since the Paris Exhibition the progress and in electrical science would have been of a general study could be resumed with much profit.

The matchless arc lamps, and incandescent lights exhibited, down to a very few exceptions, were already known. Serious trials of them had been had, and it was difficult to foresee what new experiments could be made.

Consequently the Munich Exhibition looked then as if it were destined to be only a pale copy of its predecessors, when, in reality, it was announced by its very title some as a supplement of what had been done before. Usually of the electrical transportation of power at a great distance, it was not expected that any new invention would come to light ; the purpose was merely to study in a serious manner the sundry industrial applications of electricity, and that in every way and form. It was not expected that on the apparatus, ancient and recent, exact figures, such as to constitute a precise base for future researches. The end proposed was reached, and success crowned the efforts of a diffuse light, similar to that of the day, the brightness of which was hardly surpassed in the reality. The number of lamps might have been doubled, and, without hurting the eyes, the general effect would have been greatly improved thereby.

Having said this much, let us cross the Palace in its whole width ; let us not stop to consider the brilliant palace to which we will return presently ; and, passing under artificially decorated arcades, let us enter the garden of the exhibition. There the decoration did change. Swan's lamps, disposed upon two



THE MUNICH EXHIBITION GARDENS.

rows of slender iron semaphores festooned with loops, garlands, illuminated in a very agreeable manner the small central pond, brackets and chandeliers projecting the same light, and showed the entrance of original grottoes, in which the customers were seated, while arc lamps, from the top of the lofts of the building, spread a bright light on the points on which chandeliers light would have left some obscurity. In the background was the great hall covered with canvas, which constituted in reality the restaurant itself. In its whole width it was lighted with incan-

THE INTERNATIONAL ELECTRICAL AND GAS EXHIBITION.

However much it may have been intended in the first instance to conform to the title of the present display of artificial light at the Crystal Palace and to make it an electrical and gas exhibition, in the result it would appear that the title should have been reversed, inasmuch as there is a comparatively poor display of electric light, but a very profuse show of that produced by gas. Such a transposition would more correctly indicate the relative importance of the exhibits as judged by their extent and prominence, and this idea seems to have occurred to the compiler of the catalogue, who, while preserving the order of the title of the exhibition on the title-page, has placed the gas section first in the book itself. The reason why the display of electric lighting is being made is said to be due to the circumstance that the leading electrical companies are not ready, and that the need to further advertise themselves at present has not only induced a scarcity of exhibitors in this section, but even the installations of the few who are represented were, in several instances, at the time of our visit on Saturday incomplete. Not only are the gas rivals actively pressing forward early in great strength and in nightly filling up with more of the Palace with a splendid flood of light. The electricians are in search of the north nave, many of which are apparently recently begun to make some show. In fact the, exhibition has at length assumed a condition of approximate completeness, which renders notice in order.

Keeping to the time the title of the exhibition, we will turn first to the gas section, one of the last examples of which is at present to be seen on the Alhambra court, which is situate at the far end of the transept. The beauties of these halls are fully brought out by the Vitruvium-Lee arc lamps, four of which are suspended in the centre of each, while another is placed in the hall of the Abencerrages, commonly known as the dome, which is very effectively lighted by them. It also illuminated by a number of these lamps, which are of the original Wermdorm type, consisting of a carbon rod and platinum terminal disc, are placed in the remaining three courts of the Alhambra court and in the Tropical department. Another of these lamps standards have already been mentioned in previous notices. The Werdermann-Lee lamp is a new, upon the Wermdorm and Sarting carbon rods of different diameters, the thickness of the upper positive carbon being 22 millimetres and that of the lower negative carbon 20 millimetres. The positive carbon is fixed into a metal carbon holder, the arc, as the current passes through it, being kept steady by means of a solenoid, through which the current passes, and at the same time that it strikes the arc the holder is gripped between three rollers, which are driven by clockwork. As the length of arc increases, the resistance to the current increases also, and a portion of the current then passes through a second solenoid wound with fine wire and being thus a shunt to the main circuit is the one of this solenoid is a lever arc dashpot working against the outer edge of the topmost of the three rollers. The solenoid is magnetized by the diversion of the current it presses this lever against the edge of the roller and forces the latter to slip under it, and so to release a of a proper length. When it has reached a position of this kind, which may be regulated to a thing by means of a weight, the lever becomes detached from the spring which carries the current to the solenoid and it over-balanced and depressed by an upper spring attached to it, which brings it into rollers and allows the current to pass again to the solenoid, which, as they are of definite resistance, are adjusted so as to take according to the requirements of the lamp, that is to say, to keep a steady light. The lower carbon being so much the shorter of the upper one, the arc is kept within a range of one inch in length, and as the lamp is capable of burning for 24 hours continuously, the light produced is comparatively small, but brilliant, and the cost of supplying apparatus just described is not liable to get out of order is apparent from the fact that some of the lamps in the Alhambra court were started when the others were extinguished on the 15th of December last, and are still working. Of the Siemens-Hefner-Alteneck lamps, of which there are a number in the Alhambra court, we have already spoken. The current is supplied by an "A" Gramme machines similar to those which are driven by a 25-horse power engine. Another, a number of power being retained for other machines yet to come. Of the Crompton and Rookin of the Vulcan works, upon the construction of electric lighting, his first demonstration upon the occasion of the Prince of Wales on the 6th of November, 1879 we have here lamp, and one of small intensity, is that of Mr. Crompton's own design, four of which are to be seen in the Tropical department, three of which are to be seen in from others in several important particulars. In most circuit with its enclosure to separate the carbons, or solenoid, is used and also a shunt electro-magnet or solenoid to regulate the arc in each lamp when several lamps are

Lever lamp is that it dispenses altogether with one of these magnets—that known as the shunt is regulated solely by the shunt magnet or solenoid. Superiority is claimed for this system on the grounds of economy in the utilization of resistance, and regularity in the feed of the carbons, economical as regards the current, since it does away with the constant maintenance of the main magnet or solenoid. There a great number of these lamps can be worked in single circuit by the use of a shunt box, a type of the cell-lamp. Instead of bringing the carbon points to come into contact with each other before the current is sent through the lamp, as is usually the case, the process is reversed in the Lever lamp, and the carbons are separated with each other by means of a wire acting as a lever with a fine platinum collar encircling the carbon-holder and thus establishing the circuit. Into the arc, formed of iron, having two arms working through it with large flat heads for the purpose of keeping the metal down to the lever, and underneath this bar of iron, the carbons are the poles of the shunt electro-magnet. The Lever lamp, as we have said, gives a good, steady light, are supplied with current from a Siemens machine driven by a Davey Paxman semi-portable engine of 20-horse power nominal. The Swan Electric Light, Power, and Storage Company, are illuminating one section of the Alhambra court, and those of four of the Duplex arc lamps, the current for which is driven by the engine used for driving the Swan incandescent lamps. Other sections of the Alhambra court are illuminated by about 80 of the Duplex Company's incandescent lamps, also supplied by power cash. These lamps are supplied with the current from a Martin generator, assisted by a small Siemens dynamo, and are driven by a 10-horse portable engine by Messrs. Tasker, Sykes, and Co. This engine and the machines together with the Crompton machines previously referred to are all placed in the large machinery annex at the north end of the tropical department.

Continuing our course southwards along the north nave, we next come to the Gilbert-Ayrton-Hopkinson arc lamps, by eight large incandescent lamps, which are placed in the nave and two in adjoining courts. The object of the court is to be lighted by the Gilbert Company with their new incandescent lamps placed on the same circuit as the arc lamps, the current for supplies with a current from a Gilbert dynamo machine, the peculiarity of which is that it produces a current of constant intensity, but of varying a great factor of safety. The connecting wires from the dynamo machine to the lamps are of small size, and it is shown that they may be handled with impunity, there being no danger to be apprehended from them.

Continuing in a small room in the centre of the nave, where the safety of the system in this respect is demonstrated, we next come to the Siemens arc lamps in the north nave, in what is known as the transept, are driven by a 10-horse power combined engine and dynamo by Messrs. Hammond, Hack, and Jefferies. In this nave there is the generating machinery of the British Electric Light Company, which consists of a large Gramme dynamo of a type with one as we earlier. These are driven by a Davey Paxman 20-horse power engine of 30-horse power nominal. The current is at present supplied to six Brockie arc lamps of the new arrangement, but these are to be added to by others in course of time to complete the installation. The lamps are in the centre of the nave near the centre transept.

Between the transept and the nave are placed the Edison lamps, which are exhibited by Messrs. Steele and Hiemens. These lamps are supplied with a current by the Siemens machines, while a fourth supplies about a hundred Swan incandescent lamps, which are tastefully arranged on Messrs. Steele's stands, which are tastefully large. Only 25 of these incandescent lamps are at present at the same time, as a new machine is only capable of production of the current required for that number. The Edison lamps, however, ranged in four groups, and the current can be switched off and on to any one of the four at pleasure. The machines which produce the current are placed in the west section, and are driven through intermediate countershafting by the 30-horse power engine of 50-horse power, which was originally put up to drive the machinery of the Woollen Exhibition. This engine is also driving a dynamo machine, which supplies the current to the six Blanchard Fyfe Main Company's incandescent lamps, which are placed in an elegantly organized chamber in the Renaissance style at the centre transept. This chamber is the one formerly occupied by the Prince of Bavaria, and was shown last year at the Exhibition of Art Industry at Nuremberg, where its artistic fittings obtained for its designer the highest award of distinction. The arc of electric lighting terminates at the commencement of the transept with the three of Messrs. Gerard and Co.'s arc lamps. Three of these lamps are lighting the entrance to the Fine Art Court, the Lord Mayor's Gallery, while another is to be found in the west corridor, whose the dynamo supplying these lamps is placed, and which is driven by the Gallowray engine.

The floor of the north nave is occupied by the stands of the Brush Company, a variety of electrical apparatus and accessories, the Electrical Trading Company exhibit samples of Mr. Bernhard Hurst and Co.'s electric con-

ductors, which are a wide departure from ordinary practice. The conductor is formed of a copper wire, or of several, thoroughly, wrapped with several thicknesses of cotton, and then saturated with something a mixture of paraffin and solution, which forms the insulating material. The protected wires are then twisted into a cable by an ingenious and special process, which results in compressing an ingot of lead by means of hydraulic appliances, and the lead is forced through it over the wire which has been coated with the cotton and the insulating material. This system of manufacture is claimed by the contributor to establish a high insulation without decay, and they are favourably reported upon in other connections. The Electric Installation Company exhibit some telegraphic and electrical machinery, which possess a remarkably fast electrical speed, as shown by the figures, and which could be used with advantage for their purposes as insulating ground permanent way for electric conductors, which consist of a plate of earthenware, with a groove, and the naked wires are laid in them and fixed with cement. Another exhibit is that of Messrs. Siemens Brothers, who have a large space in precise three of the north nave. Here will be found the various systems for the transmission of telegraph and telephone messages, which are to be seen overhead in most towns and the underground system of Messrs. Siemens. Grand and detailed exhibit a very useful description of the various systems for the transmission of telegraph and electric lamp standards. There are a number of stands at which electrical and telegraphic instruments of various kinds are exhibited, as well as the details relating to these two departments of applied science. Last exhibit in the north nave of electricity is will represented, but at the time of our visit there was nothing of novelty calling for notice, by which we have described. We must reserve for a subsequent article the gas exhibits in the south nave for a subsequent notice.

Electrical Review
July 19, 1884.

Louisville Exposition Light.

The Machinery Committee of the Southern Exposition met yesterday afternoon (July 9) at the building and signed the contract with the Edison Company for Isolated Lighting, of New York. The contract is the largest that was ever made for lighting a building with electric lights.

The company agrees to light the building and the annexes with 4,400 Edison lights of 16 candle power each, in other words, the plant that will be used will furnish more light than any other plant ever did. It will even be larger than the combined plant used at the great electric light exhibition at London last year.

Some idea of the undertaking may be gained when it is announced that the wire to be used would reach 40 miles in length if stretched out in a straight line. The wire is all of copper, and much of it is very thick. Its weight will be 48,000 pounds. The number of dynamos machines will be fifteen, worth about $2,000 each. To run them will require four of the Armington & Sims engines used by the Edison Company.

The cost of the entire plant will be about $100,000, and it will require about 100 men, working constantly from now until the end of the month to string the wires and put all the electrical machinery in order. The plant will be sufficient to supply a large with 40,000 lamps, as not more than a fifth of the lamps in a room are ever lighted at the same time. Here all will be burning at once. The plant will be equivalent to a gas plant manufacturing 25,000 cubic feet per hour. These figures give some idea of the enormous supply of light that will be required and furnished; but no one can really comprehend how much light will be necessary until the grand opening is entered and beyond then it may be understood what the necessities are.

While the 4,400 lamps are thought on a careful estimate by experts sent out by the lighting company to be more than sufficient to light the building brilliantly, there is no doubt that many exhibitors will want to make a specially brilliant display over their exhibits, and the electric light can easily be furnished from the mains already laid. Edison himself will be here to superintend the completion of the work and the lighting of it. The advantage of the incandescent electric lights in such a building as the exposition building cannot be overestimated. If generates no heat, nor does it absorb any of the oxygen of the air. Were the building lighted by gas the consumption of oxygen would probably equal the amount that a crowd of 25,000 people would use up. The display of electric lights will certainly be beautiful, and those who see it will have the satisfaction of knowing that they have seen the largest display ever made.

The Electric Light Company will make special exhibits of electric motors and of submarine lamps, which are very wonderful and interesting.

Other incandescent light companies will make exhibits of their lights here.

The courts and parks of the exposition will be lit with the Jenney arc light of Fort Wayne, Ind. The company will furnish 75 arc lights of 2,000 candle power each.

Menlo Park Scrapbook, Cat. 1017

No. 11G. "Electric Light"

This is the seventh of nine scrapbooks containing clippings about electric lighting. It covers the years 1880-1884. There is also one clipping for 1877. The book contains approximately 140 unnumbered pages.

Electric Lighting

Call it - 11 G

4 R 13.

THE METROPOLITAN, OCTOBER 14, 1882.

The Electric Light in Clerkenwell.—All public bodies having the care of important thoroughfares are somewhat perplexed at the present time as to the best and cheapest method of lighting. Electricity and gas are contesting side by side, and the former can scarcely be said to have sufficiently advanced to ignore the claims of the latter to public support. Indeed, a question which in the minds of many is only at present partially decided is, whether by the same expenditure upon gas, equal results may not be obtained as from electricity. The Lighting Committee of the Vestry of Clerkenwell has, under the leadership of its chairman, Captain G. A. Potter, been endeavouring to solve the problem, and obtained the permission of the Vestry to try both gas and electricity under conditions which, it is hoped, will indicate with tolerable accuracy the relative merits for two modes of lighting. The committee decided to employ for the purposes of these tests an incandescent electric lamp of greater power than those used by Edison on the Viaduct, and an incandescent gas light which appears to be an old friend in an improved form. So far as the question of electric lighting was concerned the views of the Lighting Committee were met by the Weston Maxim Company, who offered to supply engine, machines, lamps, &c., and to light for a period of twelve months the line of thoroughfare known as the Pennonville-road, from the "Angel" to King's-cross, *for £250*. The lamps were to be incandescent, producing a light equal to 50 candles, and two of each were to be placed on each of the existing lamp-posts. This offer the committee accepted, and further more stipulated that the taking up of the roads for laying the cable, &c., should be done by the Vestry's paviors. The necessary preparations were so far completed that a preliminary trial of the lighting was made in the evening of the 6th inst. The result was most satisfactory, for no part of the road appeared to be in darkness, neither was a lot of power wasted on the adjoining houses, such as one may witness when powerful arc lamps have been used in ordinary thoroughfares. The light was steady and not at all unpleasant to the eye, while it power was fully demonstrated when the current was shut off and the ordinary gas lamps again lighted. The experiment will cost the parish nearly three times the price of gas, but the lighting afforded is nearly ten times as great. The works in connection with the incandescent gas light are not yet completed, and we, therefore, defer full details for the present. The matter, however, stands thus:—In the early part of the summer Messrs. Hegan and Co., of Moorgate-street, who have acted as the agents of the patentees, placed themselves in communication with the Vestry and an exhibition of the light was subsequently given at the Vestry Hall. Messrs. Hegan thereupon submitted a request that the Vestry would grant permission for a certain section of the parish to be lighted by their system, the whole of the expense, including the breaking-up and re-making road and footways, to be borne by themselves. The Vestry was satisfied with the lights exhibited that they gave consent for the trial to be made, and referred the whole subject to the Lighting Committee to arrange. The committee agreed that as Messrs. Hegan had works on Clerkenwell-green, their pipes should start from that point and be continued up St John-street-road to the Angel. Furthermore that all road work should be carried out by the Vestry's paviors, Messrs. Hegan depositing £100 as security for such expense. The patentees were also bound down to remove all their plant at the expiration of the experiment, providing the Vestry were dissatisfied with their system. These terms were accepted and embodied in an agreement, but owing to the patentees wishing to form a company, or some such like cause, the work has not yet been carried out. We hear, however, that the gas company has bought the patent and intends to fulfil the contract made between the Vestry and Messrs. Hegan. Briefly speaking, the system consists of gas and air being driven through separate pipes and uniting in a patent platinum burner, whereby both flame and smoke are avoided, and a soft, but withal powerful, light obtained. The cost will naturally slightly exceed that of the ordinary gas lamps, but the result, it is asserted, will more than compensate for the additional outlay.

St. George's Vestry and the Electric Light.—On Monday night, a committee of the whole Vestry was held in the Board-room, Borough-road, to take into consideration the Electric Lighting Bill, 1882, and to take such steps in relation to the same as might be deemed advisable. A special meeting of the Vestry was held afterwards, to receive the report of the committee. The rector, the Rev. Harman Casali, presided; and there were also present—Messrs. R. D. Hilton, Emary, Gillett, Bacon, Yates, Sinden, Heather, Wm. Taylor, Dowse, Mitchell, Bartley, Beaver, Meredith, White, and Dr. Smith.—Mr. Yates moved the adoption of the following recommendation of the committee:—"That in the opinion of this Vestry it is not desirable at present to apply for a provisional order or license for the electric lighting of this parish."—Mr. Sinden seconded, and the motion was unanimously agreed to.—Another recommendation of the committee was—"That unless the Electric Lighting or other companies applying for provisional orders, or licenses (under such clauses as provided by this Vestry, the Vestry Clerk be empowered to instruct Messrs. Simons and Co., Parliamentary agents, to oppose the schemes."—On the motion of Mr. Bacon, this was also agreed to, and the Vestry adjourned.—It will be seen in another column that steps are being taken for a conference of delegates from all South London parishes on the subject.

The Swan Light at the Paris Opera House.—A very successful installation has just been completed with Swan lamps and Faure accumulators in the Paris Opera House. The lamps were first shown to the public on Friday, September 29. They have been placed in several parts of the building, but more prominently in the foyer, the extremely elaborate decorations of which have been entirely spoilt by the ruthless effects of the electric light the foyer with gas, ten chandeliers, with 48 lights of 20 candles were used—equivalent to about 9,600-candle power. Two of these chandeliers have been fitted with 48 Swan lamps each. There were run up to about 40-candle power, making a total of 2,840 candles for the two chandeliers—almost exactly equal to the eight remaining gas-lit chandeliers. The effect in the neighbourhood of the electric light was extremely marked, and the representatives of the Opera House who witnessed the trial expressed themselves extremely pleased with the result. We may add that all the main cables were covered with lead, and every lamp was protected with fuse circuits to avoid any possible chance of fire.

A Warning Lamp.—An ingenious adaptation of the electric signalling system has been effected in connection with a lamp which is made to give notice of either a burglarious entrance into or a fire upon premises where it is employed. The apparatus consists of a small battery with wires leading to attachments on doors and windows, and other wires communicating with the lamp which may be placed either inside or outside the premises as preferred. If a door or window being moved, after the apparatus has been set for the night and the lamp lighted, a red glass disc is released by the aid of a small electro magnet placed within the lamp, and a red or danger signal is thus given, the light having previously been white. For fire purposes a special thermometer is used, and when the raised temperature causes the mercury to rise, metallic contact is made, and the lamp at once shows the danger signal. The lamp is being shown at No. 23, Lidgate-hill.

THE INDIANAPOLIS JOURNAL.

THE ELECTRIC LIGHT

In Successful Use in Many Places in the City of New York.

W. A. Croffut's Letter.

[In eight columns now since I said anything in these letters about electric lighting, that time tremendous progress has been made, and it is not worth while for any letter-writer to ignore it. Of the achievements of the United States company it is unnecessary to speak, for its blazing arcs illuminate the streets and burn in the cupolas of the towers, but in a few days there were a dozen companies in full operation to furnish any city with the incandescent light—this it is, in light interiors with small shifting bulbs like gas lights—but at this moment Edison's company is the only one actively in the field. It not only occupies the field, but it comes near filling it. Mr. Edison has done all he ever promised to do and his promises usually are paramount, but he has not done it so quickly as he anticipated.

The 1st district of this city is lighted—lighted apparently to the satisfaction of all, besides. Eighty-one buildings are now using the electric light exclusively, and more are being added every day. Only one engine is being used at present, and 16 dollvers all the time. Four more were purchased, and more. The last one was to be delivered on the 3 per cent., but the force from the engine-room now is only 1-000th of 1 per cent. Mr. Johnson tells me—which implies pretty nearly perfection. The light actually furnished is about nine lamps to the horse-power. The six engines in the Pearl-street station were bought not to run uniformly, and are being supplied with all services. Next week, Monday, will be the 4 lighted together, and 400 buildings will be supplied. Then 4 more, and those already on the circuit. The next district to be lighted will be the heaviest in the city—that of which Madison square is the center.

The Times is lighted on the circuit of the first district. I went into the counting-room and found the room last night in beautiful order. They spoke warmly in its praise. "The best artificial light I ever wrote by," said the managing.

The Herald and Telegram establishment is lighted wholly by the same light. I walked over there after completing the above canvass, and saw the editor, Mr. Cannon; and the business manager, the foreman and several of the editorial writers and reporters. They all, now, said the foreman, "as if we could never be satisfied with any other light." The room was clear, steady light, and the temperature of the composing-room, usually too high, is very much reduced. We shall never go back to gas. As to the cost, I don't know. If it is more than gas, I think our men would be willing to pay the differ; more but they say it is cheaper than gas. The office is about 100 feet square, and everywhere the bulbs are hung down from the thickest parts, each surrounded with a large tin shade.

The testimony of the business manager is the same effect, but he added, "It is not only better than gas, but cheaper. Being one of the first district, the Herald is lighted from an isolated plant that is, we furnish our own electricity. We have two engines, one local engineer, engineer, and two firemen. The interest on investment and all, amounts to about $7,000 a year. Our gas bills for several years have been $12,000 a year."

The Edison Isolated Company, besides the Herald building, has already lighted about 100 buildings, mostly manufactories throughout the country. These include the Chicago Daily Inter-Ocean, Cincinnati Commercial, Public Ledger, Ohio State Journal, Brooklyn Eagle, Cincinnati Commercial, Public Ledger, Philadelphia, and Boston Herald.

The largest plant is that of the new steamer Pilgrim of the Fall River line, the largest steamboat in the world.

Said Ralph Meeker of the Herald to-day, "It is as much better than gas as gas is better than tallow candles."

JANUARY 5, 1883.

THE TIMES.

MR. EDISON.

[FROM A CORRESPONDENT.]

The development of Edison's system of electric lighting, of which so much was heard in London during the early part of 1882, has since then almost exclusively engaged the attention of the inventor. It is well known that the Edison system comprises the manufacture, distribution, and measurement of electricity by means of a motor, and the sale of light and power to consumers on their own premises. In New York, the central station in Pearl-street was opened on the 4th of September last, since which date there has been no intermission in the production of the current, either day or night. The pressure on the 30 miles of mains is constant and equal, and the additions to the system average something like 80 lamps per diem. The remarkable simplicity of administration cannot fail to impress even the ignorant visitor. The regulation of the system is carried on by means of an automatic device, by which when the lamps on the system are below their proper candle-power a green lamp is switched into circuit, and when the candle-power is excessive, the fact is indicated by the display of a red lamp. The lamps are perfectly steady, and are maintained at a somewhat greater candle-power than the majority of incandescent lamps in England.

The success of this practical trial of the system is now beyond question. Not only are the inhabitants of the district daily demanding the supply of the light, but stations up town in New York, as also in Boston, Chicago, and Denver, are already in contemplation.

Not less successful is the Edison Isolated Company's organization for the supply of light to mills and factories, &c., by means of plant on the premises. The company declared an annual dividend at the rate of 10 per cent. during the month of November, and in so doing eclipsed the distinction of being the first electric light company to pay a dividend on the results of electric lighting pure and simple, excluding profits on manufacture or sales of concessions.

The Edison Lamp Company, whose factory is at Newark, in New Jersey, possesses an establishment which is remarkable even in the land of ingenious processes. The Edison lamp passes through more than 200 stages during manufacture, many of which are automatically performed by the agency of electricity. Mr. Edison's mind is stamped on many of these processes, the exquisite simplicity of which elicits admiration from the engineer. Edison turn out 10,000 lamps per day, and according to Mr. Upton, Mr. Edison's manager in the undertaking, the resources of the factory are sufficiently capable of accommodating the demand.

At the Edison Machine Works, at Goerk-street, New York, the dynamos, large and small, are manufactured. Since January of the present year more than a thousand shipment to London; four were despatched for Milan, where a central station on the Edison system is being organized by Professor Pacinotti.

The factory of Bergmann and Co. is exclusively devoted to the manufacture of switches, fittings, sockets, regulators, and other details of the complete Edison electric light system. Here also the application of electricity as a motive power and lighting agent was manifested in an impressive manner. Mr. Edward H. Johnson, whose name is well known in London, together with Mr. Edison is continually at work improving the minutiæ of the system, it was shown a simple screw, the sole survivor of 42 separate and discarded models, which had failed to satisfy Mr. Edison's standard of efficiency. Details of the system are accurately and constantly subjected to the fierce light of criticism, and continually being brought up to the requirements of the inventor. As an example of American manufacture and administrative power, the following is one instance:—An order for light the Boston Bijou Theatre with 650 lights was completed within 11 days after receipt of the order. The theatre was wired, the boilers and engines were placed in position, the current turned on, and the special regulating system necessary for switching the lights on the various circuits on the stage or auditorium not only devised and manufactured in New York, but also in position. The writer was present at the opening of the theatre when different acts and scenes successively produced and all the necessary scenic effects obtained by the aid of the Edison light alone. The theatre was better lighted than the Savoy in London, and the regulation of the lamps seemed to be under more immediate control. The feasibility of accomplishing this work in so short a time arose greatly from the absence of such complications as the legislative restrictions as in England impede the progress of electric lighting there.

During past years Mr. Edison has suffered from fulminations, premature, inventions of his inventions, and for some time, therefore, he has remained silent, reserve present information as to the progress of his inventions. Some months have elapsed since the Edison system was first shown to the English public at the Crystal Palace, and, as is well known, it is operating in various places. Since then Mr. Edison has, however, not been idle. He has made remarkable discoveries, the effect of which is greatly to increase the efficiency and reduce the cost of the light. These discoveries include a considerable improvement in the dynamo and the invention of a more economical lamp of very high resistance. It is interesting to know that in England and the capacity of the machines does not involve the disuse of any of its parts. Nothing is made obsolete. A simple and inexpensive addition increases, to use popular language, the electrical horse-power, and the use of the improved lamp more light is obtained from a given quantity of electricity than is now the case.

Patents for these and other improvements have already been applied for, both in England and the States, and the English company will shortly give a public demonstration of the new inventions. Mr. Edison's knowledge of the conditions of the electric light question in England is complete. To his mind the price of gas in England is the one factor in the problem which requires solution. It is this problem to which he has applied himself with so much success.

THE PRESENT POSITION OF ELECTRIC LIGHTING.

[FROM A CORRESPONDENT.]

It is now a matter of surprise to many that the progress of electric lighting has been so slow. The superficial observer of two years ago was impressed with the idea that perfection had been reached, and henceforth there would be a rapid supersession of gas by the new light. It will be well to discuss briefly one or two of the causes which have led the non-scientific public astray in their conclusions as to the capabilities of the electric light. The greatest enemy to electric lighting has been speculation. It amuses even those who for years have been students of finance to see how admirably the financial affairs of certain, large companies have been managed. Those companies have been treated, with an enormous capital, to manufacture and install apparatus, which to those who understand such matters, was seen to be applicable, for a very moderate extent. A new form of obtaining revenue was found in the selling of concessions—a method, again, of limited application and doubtful expediency when the future as well as the present is considered. Usually a manufacturer is willing to pay commission to agents, but here the order of things was reversed, and agents paid large sums to manufacturers in order to become agents. Such a course might with advantage be pursued in the case of absolute monopoly, but in the face of the keenest competition it is absolutely fatal. The apparatus manufactured, saddled not only with the ordinary manufacturing profits, but also with the interest of the capital sunk by the concessionaire in purchasing the concession. We need not point out that this term "concession here," when analysed, indicates something totally different from the term "concession as generally applied to gigantic engineering works in the shape of railways and canals in new and sparsely populated countries. The electric light concessionaire has been principally concerned with a system of lighting termed arc lighting, that is, lighting by means of arc lamps. Such a system is not applicable to ordinary dwelling or bed rooms, but, undoubtedly, more economical than any other system; but few people care about a light equivalent to two or three thousand candles during dining, drawing, or bed rooms; then, again, these lights are not altogether unexceptionable in point of beauty. They have an objectionable glare of blinding when you particularly seek quietness, and of casting a flickering and flickering light when you ask for perfect steadiness. Till the result of the long series of experiments carried out by Edison and Swan in England, and the almost contemporaneous experiments of Edison in America pointed out that a small lamp to give light of similar intensity to that of gas was practicable, the concessionaires for lighting seemed to be independent upon the degrees of perfection which could be given to arc lamps. Directly, however, the results of these experiments were published, and incandescent lamps were seen and tested, those who understood the matter saw that these lamps were suited to take the place of gas, and that the future of electric lighting was closely connected with the incandescent as opposed to the arc system. Thus, the enormous speculation in arc systems was incomprehensible, and by forcing into notoriety a system which has small value, great harm was done inasmuch as a system that is incomparably its superior, viz., We would not be understood. The arc system has a place, but

of usefulness, but when compared with that of the incandescent system the field is indeed limited.

A second preventive to rapid progress was due to legislation. Existing laws operated against the introduction of the new light, and it was not till the last Session that a Bill was passed to increase facilities and remove obstructions. There has not yet elapsed sufficient time to allow the legal conditions imposed by this Act to be carried into effect. The necessary notices have been duly given, and drafts' provisional Orders, adapted in accordance with the requirements of the Act, to about one hundred and fifty cases, so that early next Session several of the better-matured schemes will, no doubt, be granted. We have reason to know, so far as having carefully considered the draft, will enable one to know, that the drafting of the order has been done in a very able manner, and an attempt has been made to establish a model order, the chances of which duly consider the welfare of the companies, their duties and privileges, while at the same time guarding the public against imposition and loss.

We are glad to notice that a few of the local authorities are applying for orders. It cannot be too often or too strongly impressed upon the various authorities that before committing themselves to any company they should take an opinion from those competent to give one. Unfortunately the number of men whose opinion on such a subject is worth having is few, and great care should be taken in the selection of consulting engineer.

It may be surprising again to learn that, even had facilities existed for the introduction of the electric light as far as regards legislation, it would till quite recently have been impossible to carry out any work on a large scale. The dynamo machines required to produce the electric current were practically, models, and entirely useless for lighting on an extended scale; Mr. Edison, indeed, constructed machines to supply currents to a thousand or fifteen hundred of his lamps, but we think the general opinion is that the sixteen candle lamps as seen at Holborn are of too low a candle-power, preference being given to the whiter light of the twenty candle-power Swan lamps. This question of candle-power has little to do with the value of the Edison or any other lamp, because it requires only a modification in the manufactors to increase or decrease the candle-power. Mr. Edison can give lamps of twenty, forty, or a hundred candle-power, and no doubt will do so if public opinion favours the higher intensity. Mr. Crompton's machine, if report is trustworthy, is far surpassed by that of Mr. J. E. H. Gordon, which has been constructed at the Telegraph Construction and Maintenance Company's works at Greenwich. This machine is compact, strong, said to be economical, and will supply a current for six thousand Swan lamps of twenty candle-power. The design of this machine admits of much larger machines being constructed, and we have heard of one to such items of cost as may have been overlooked; supply twenty-four thousand lamps. Nor would a machine for this purpose be unwieldy. Three and many towns where two of the six thousand lamp machines would adequately supply all that light required. The machine has the disadvantage—if disadvantage it is—for to what is technically known as an alternate current machine, and cannot be used for the transmission of power, or without mechanism, for the charging of accumulators. There is no doubt this machine has made its appearance at a very opportune moment, when large designs are in contemplation. That other large machines with direct or alternate current will be constructed hereafter is certain, but we are dealing with the present. Before long has been made to accumulators, or secondary batteries. The popular conception of these adjuncts to electric lighting is ludicrous.

THE PROVIDENCE EVENING PRESS

CONGRATULATORY NOTICES
Of the Electric Light Competition
Held at Providence, R. I.
The Electrical Engineer, of New-York, the leading electrical paper of the country, in a recent issue says:
"We have from time to time commented upon the work which the American Electric and Illuminating Company has been engaged in, in introducing the Thomson-Houston electric lighting system in various New England cities, and commended its vigorous methods of dealing with difficulties. It has acted up to the position with which it has been set in establishing itself in Providence, and have inferred ourselves as to the facts in the case.
It seems that in the Congress, since recently elected, issued a building in Providence, suitable for an electric light station, equipped with steel lattice of two hundred feet, and the New Armington & Sims engine of fifty horse-power each, and the necessary dynamos and all the apparatus of electrical excellence for a full two hundred light plant; expending in actual cash over sixty thousand dollars in the work, every dollar of which has been paid. Having thus established with its customers in a business way; it asked the city council for authority to run its wires overhead instead of as now in the streets. Its petition was referred to a joint special committee of both branches of the city council, and a hearing was had on last week, Nov. 21, that committee gave a public hearing, at which the petitioners by attorney and any who desired to oppose, could be heard. The city of Providence, unlike many cities, that has air and hot water should be more extensively used, and no doubt the architects of the day is leaning in this direction. Health and comfort will precede excitement when this happens, other things besides the Street can be considered. Our own impression is that as yet the absolute cost of electric lighting is not sufficiently constant the comparison with that of gas is misleading. We do not believe, with other electricians, we give figures prepared by perhaps the greatest authority on such matters who has taken for what they are worth. The "units of consumption, on the side of gas, "the cubic foot of gas consumed per hour, equal to a light of sixteen standard candles;" on that of electricity "76 volt-amperes of electric energy, equal to giving a light, with a Swan lamp, of 12 candles per hour." The various considerations are given under heads of "cost of supply, how charged for, cost of manufacture, maintenance, management, repairs, and profit. Altogether the estimate is decisive as to the superiority of electricity, the cost of gas being 1900 percent more than that of electricity, that of electricity the same, with 21 per cent. profit.
If this estimate is approximately correct, it will be seen that there is a fairly large margin to meet or are unknown. The work at the New Arcade Castle, which will at first be only temporary, will be watched with great interest, but we think Mr. Crompton, who has done more for the practical introduction of the electric light than any other engineer, is little likely to neglect any precaution necessary for the work to prove successful. The electric light is being introduced into Windsor Castle under the able superintendence of Mr. Massey. In such places as these there can be no reason why, when the original balance-sheet is made, a much truer idea of cost should not be obtained than under the idea of cost in dotted from estimates made under exceptionally favourable circumstances.

Journal, Feb. 4, 1881.

ELECTRIC LIGHTING IN THE CITY.—As was announced by us some time ago, the Commissioners of Sewers of the City of London are about to try the experiment of lighting by electricity some of the principal streets within their jurisdiction for a twelvemonth, and for testing side by side, as it were, three of the most accredited systems on a scale and under conditions which must make it crucial as regards the present conditions of the problem. The task will not be the least attempt of the City in this direction. Acting on the report of their engineer, Colonel Haywood, the Jablochkoff system was tested on the Holborn Viaduct from the 4th December, 1878, to March 9, 1879. During that period sixteen electric lamps were used in place of eighty-six ordinary lamps, fourteen being placed at equal intervals on either side of 473 yards of street, and one lamp at each end of this distance in the middle of the roadway. The lamps illuminated about 888 yards superficially, and were kept burning seven hours per night at a cost of 2d. per lamp. No photometrical observations were made by the Committee during this experiment, because the Metropolitan Board of Works were conducting simultaneously the electric lighting of the Thames Embankment, under exactly similar conditions, and some scientific officers of the Board came to the conclusion that the illuminating power of the light, when mentioned, was about five times that of ordinary gas, and when enclosed in the opal globes used on the Viaduct seven twice as much, while the actual cost was nearly four times as much as gas. The companies have greatly reduced the cost of producing the light since then, and of course there is a more formidable competitor with gas. Under the new arrangements the Commissioners of Sewers have decided to try the Jablochkoff, the Brush, and the Siemens systems. The first will be applied to Southwark Bridge, Queen Victoria Street, and part of Queen Street; the second, to New Bridge Street, Ludgate Circus, Ludgate Hill, the east side of St. Paul's Yard, and thence along Cheapside to Bow Lane (King Street); and the third to the north of Cheapside, the Poultry, King Street, Guildhall Yard, Moorgate Street, Lothbury, King William Street, and Gracechurch Street. The contract price is £2250 for the Jablochkoff, £1410 for the Brush, and £2700 for the Siemens districts. It was intended that the experiment should commence on the 1st of March next, but the severe weather has so delayed the preliminary work that it is doubtful whether necessary arrangements can be completed by then. The Commissioners, in order to bring their arrangements have utilised the best data at their command in regard to guaranteed illuminating power of each lamp, and the superficial area of roadway it will command, but only careful scientific observations will determine the exact photometrical value and economy of these competing systems.

THE SATURDAY EVENING CALL.

THE EDISON ELECTRIC LIGHT.

Yesterday it was announced that the Edison electric light company is now fully formed, composed of our leading business men and capitalists, with a capital stock of $50,000, nearly all of which has already been subscribed. It is proposed to place a plant in actual operation on one of our business streets and furnish the public with the inconsistent light.

To those who have not seen the incandescent system, an explanation will be in order. The light is contained in a small vacuum glass globe, about the size and shape of an ordinary pear. Contained within the glass is a fibre of bamboo, bent in the shape of a loop. The bamboo, previous to its introduction into the loops, is scraped to the right size and weight, placed in a nickel mould, bent in loop form and carbonized. After this, the metal points, which conduct the electricity to and through the carbon, are electroplated into the carbon. The glass globe is then exhausted of air and sealed up to form a perfect vacuum. . .

The lamp being completed, it is tested by instruments capable of ascertaining its resistance with po-itive accuracy. The means of economy is found in those lamps having a resistance of about 140 ohms, all others are thrown aside and used only for experimental purposes. Mr. Edison has surrounded his system of lighting with safeguards against all possible danger of fire by a series of wires are called "safety plugs," which are placed so as to control each and every lamp, from the best one to the machine which generates the electricity.

These safety plugs, which are of lead, melt at an excess of heat in the maine, and obviate all danger of fire by destroying the electrical circuit in that branch. The beauty of the light consists in its antiflam steadiness, absence of heat (there being almost one-sixteenth the heat generated as from a gas flame) and its entire freedom from all noxious gases which are noticeable in all other artificial lights. Parties who have seen it pronounce it the finest artificial light in the world.

Danger to life is absolutely impossible with this system, as in no case is a stronger current than 110 volts of electromotive force used. The human body requires about 1,200 volts to destroy life, which is done, in fact, to its high resistance to the passage of the electricity. The mild current of the Edison machine will in time be used directly as one of the best medical agents for the curing of nervous diseases.

The dynamo machine, in use by the Edison company, is the entire product of the brain of Mr. Edison, and differs in all essential points from all others. The armature is built up of plates of sheet iron, insulated by sheets of tissue paper, and bolted firmly together. By means of this arrangement, the armature which revolves in the magnetic field is kept perfectly cool and nearly every particle of the electricity generated is utilized in the production of light. By means of the construction of his dynamo and armature, Mr. Edison utilizes almost every atom of the electricity generated, which he converts into light. In no other electrical machine is this possible; the highest results which have been obtained from careful tests having given not to exceed fifty-five per cent. Scientific men who have given us the subject of electricity the study of a life time, all unite in pronouncing the Edison system in every respect the most complete in all its details.

Locals is specially favored in being the first city of its size to obtain the privilege of introducing the Edison light. From reports from the district in New York City, which was lighted for the first time on September 4th and has been in continuous operation ever since, the light is giving universal satisfaction, and hundreds of applications are daily received for the light in other portions of the city.

It is probable the Edison light will be in actual operation in Locals in about six weeks' time, when the unanimous verdict will be in its favor.

Snow, May 27, 1877.

THE ELECTRIC LIGHT AT CHATHAM.—After several experimental attempts to utilize the electric light in Chatham, it appeared that the authorities have now succeeded in obtaining a satisfactory illumination of the large building of the Brush Company. The apparatus used being supplied by the Brush Company. The light is supplied by 12 lamps, of 2000 candles each, and is worked by a 14 horse-power engine.

THE ELECTRIC LIGHT AT LINCOLN.—The first attempt in Lincoln to use electricity as a means of lighting large workshops has been made by Messrs. Hoe and Co., of the Globe Works, and the experiment has proved an unqualified success. The Brush system has been selected by the firm, and the spacious workshop devoted to the fitters, turners, and erectors—which in consequence of its great size gleamed offered the greatest difficulties in the way of complete utilization of the light—has been the first dealt with. . . . .

IRON. JULY 20, 1881.

THE FITZGERALD ELECTRIC LIGHT.—A demonstration of the Fitzgerald electric light took place last evening, at the works of the Fitzgerald Electric Light and Power Company, No. Gray's Inn Road, Holborn. The light is one of incandescence, and is produced by carbon loops, the carbon being prepared from vegetable fibre. The carbon is placed within a small globe, from which the oxygen has been previously exhausted by chemical means, but it does not burn in a perfect vacuum. The Fitzgerald electric machine, which was described and illustrated in *Iron* for the 4th March last, was not used upon the present occasion, it being stated that it had not been completed. The Edison machine, capable of producing a continuous current of uniform employed and a mild and pleasant light was produced, such in fact as enabled reading or writing to be carried on with comfort, particularly with an opalescent globe over the lamp. The light can be increased by increasing the number of the carbon loops. It was demonstrated that an available light could be produced, sufficiently economical for interior illumination.

OCTOBER 24, 1882.

THE KANSAS CITY DAILY TIMES.

ELECTRICAL EXHIBIT.

THE WONDERS OF THE CRYSTAL PALACE AT MUNICH.

A Curious Piece of Architecture—The Building Itself Picturesque—A World by Itself—Aerial Costumes—Curiosity Notes.

[Special Correspondence Kansas City Times.]

MUNICH, Sept., 1882.—In the building which for some weeks almost every year is much frequented, while all the other time it stands dead and forsaken, there are, since the middle of this present month, active life and doings. The cause of this motion is the electrical exhibition.* Every day, in the evening, the surrounding streets are occupied by hundreds of people, who partly admire the electrical street illumination, and partly look at the wonders in the interior of the building. Before we also enter let us take a glimpse at the exterior of the building and its history.

The "Crystal Palace" bears its name with right, for the walls and the roof of the colossal building are formed by nearly 80,000 plates of glass, which are contained by an iron skeleton full of 3,000,000 pounds weight; the edifice has a length of 800 feet; in the centre a breadth of 300 feet and an area of 300,000 square yards. The Crystal palace, originally built by Voit, was constructed October, 1853—January, 1854, by Kramer-Clett, on the site of the palm house in the botanical garden, and was only in use for the industrial exhibition of 1854, but when it was to be taken down it appeared that the cost would be more than the worth of the material, and since that time it has been used for various purposes and for all exhibitions.

WHEN OPENED.

The electrical exhibition was opened on the evening of September 16, in the presence of several thousand people, by Luitpold, Prince Theodore, the representative of his majesty the king. About 1,000 particularly invited guests assembled at 7 o'clock in a separate room near the entrance. There were present the ambassador of France, Austria, Holy and Russia, the president of the ministerial council, the highest civil and military officers. A short time before the arrival of the princes Count Lerchenfeld and the Duke of Braganza appeared, and at 7:30 Charles Theodore drove up in full state. He was received by the committee and conducted into the gallery of the assembly, while music was intoning a festival overture by Lachner. At the end of it the president of the committee, Dr. Von Steinheil, delivered a short speech and proposed the illustrious account of which cannot be given on account of the crowd and time. He spoke first of the great hour of opening; then of electricity's wonderful power, and stressed the importance of electricity in their applications; conquered our scientific asset at electricity with that of our materials; expressed the belief, that electricity soon would be accessible to everybody, and then the importance of Munich as being destined to become the centre of this new industry, and she work, and directed the request to the chief that he might open the exhibition in the name of his majesty, who had accepted the protection of it. . . . .

AT HIS DISPOSAL.

The duke replied: that it was the wish of the gracious king, has charged him to express his majesty's satisfaction in his mind with these high exhibition for electricity. The high importance which the branch of physics in science, in industry, even in all social concerns of the human race generally has attained, as in the life of the single individual, has been obtained by travelling. Not only the scientific but every cultivated man will await with interest the result of this exhibition, may it bring information in him who is research in the special study, and offer new marks to the creating genius. I declare the exhibition opened in the name of his majesty the king of Bavaria. . . . .

Prof. Hecker gave a toast which was very appropriate for the occasion, and three cheers were given for the sublime protector of the exhibition, of which all the assembly connected, whilst music was playing the national hymn. In company with Dr. Steinheil, the duke took a stroll through the exhibition building, which occupied half an hour, whereupon the guests went into the theater of the exhibition, which was electrically illuminated. . . . There were executed some night tableaux composed of the leading dances of the ballet corps of the Royal theater. The charming forms in their aerial costumes, Bacchic crowns and connected by colored bands and pearl strings by the beams of the electric light, glistening in many colors, formed ravishing groups, the like of which, perhaps, never before the feast of his majesty. The tableaux contained played in the national hymn, which concluded with great enthusiasm. After a short duration of the illumination of the exhibition another half an hour in the building, whilst the gardens in the rooms in vain expected the illumination of the streets. It could not be executed, because the machine was not finished. . . . .

A WALK IN.

If as we now walk in. On entering the interior we are struck by the numerous rows of columns of magic. We are in a garden like Schönbrunn or the most where, with its riches and its richer. Groups of figures, the most beautiful the most beautiful plants and ornaments of all imaginable kinds are intermingled with the other objects of the exhibition. Opulent ordinances surround in bright clusters the gallery, which, with its flowers and its plants, is a regular silk arbor. Under fan-palms rises the king's throne, the splendid portrait of the exhibition, the king of Bavaria. The background of the throne is a flower panorama, which contrasts advantageously with the deep green of the plants. Adjacent to the throne is a rare stone, our scholars have perfected. The throne is surrounded by the orchestra of the band, but he scarcely knew what he should do with it. . . . . The brilliant scenery of the whole is the full moon, which, at the command of the assembly, rises in the blue heaven. The flowery bandages of the gallery are reflected in magnificent green, and the whole is a light scene of the most charming effect, but through the spectres are brightening and flowering bandages of light, and thousands of figures move past like shadows, and we enter the dream. Suddenly we are aroused by the ringing melody, which sounds from the orchestra. The gallery is filled by the admiring multitude who stroll there and through the building examining the different inventions of genius. . . . .

Adjacent to this parlor is a magnificent reading room and library for the benefit of all the visitors. This room is also illuminated by our genius' light, and contains a large table surrounded by chairs, for the benefit of the tired and weary who sit down, read papers, or write letters to their loved ones at home. In this reading room you can see all the papers of the continent. The Times and Post of two; those are the London Times and the Kansas City Times. The latter I found myself in the enterprise, and directed the Kansas City Times becoming the general organ of the English speaking people. This organ is a world of its own, and our great American genius, Edison, the best inventor of it. My next letter will be to the business and social life of Munich. G. O.

THE PROVIDENCE MORNING STAR.

THE CITY FATHERS.

They Meet and Count the Votes for Chief on Tuesday.

A Victory for the New Electric Lighting Company.

The Mayor Vetoes the Intelligence Office Bill.

The board of aldermen met at a few minutes past 10 o'clock yesterday forenoon, and ward called to order by his honor Mayor Heywood.

On motion of Alderman Burnham the reading of the minutes was dispensed with.

Petition of the assistant postmaster, the following petition of the American Electric Lighting Company, was received:

The undersigned, citizens of the city of Providence, having a knowledge of the merits of the system of electric lighting of the American Electric Lighting Company, hereby respectfully represent that the introduction of said electricity in street and municipal lights would be a benefit to the city.

PROGRESS IN THE APPLICATION OF ELECTRICITY SINCE THE PARIS EXHIBITION IN 1881.

The Paris Electrical Exhibition of 1881 was a fair representation of the condition of electrical science at that date. The practical developments which were there foreshadowed were great as to lead some one to speak of that Exhibition as being the birth of an infant which even at its birth was a giant. A number of letters appeared in these columns which chronicled the condition of the science and of its practical applications, especially to the electric light and the transmission of motive power. Although the time which has elapsed has not been memorable for any discovery or invention of great importance, yet it will be a matter of interest to look back and see what has been done in the practical development of electricity.

Since the date of the Paris Exhibition the principal advance to be recorded in connexion with electric lighting is the more complete working out of the incandescent lamp. The conditions of manufacture required to insure its lasting, to keep the vacuum perfect, to prevent the filament from breaking, and to keep the glass globe from being blackened, have been successfully studied. But there is very little to chronicle in the improvements in arc lights. An arc light consists of two carbon rods between the points of which a current of electricity is passing maintaining a bright arc of light, while at the same time the positive and the carbon rods are consumed at an intense white-ness. Meanwhile the carbon rods are consumed; and the difference between the most copious consumption in the mode of keeping the carbon points at the proper distance apart at the in this way. This "feeding" of the carbons is generally accomplished by the weight of that part of the lamp which supports the upper carbon, and in most systems it is only the upper carbon which moves. In consequence of this the point where the light is most gradually sinks, and for this reason very large globes are required to surround the light. When the public have seen a more ordinal it will certainly demand a lamp with the light in a fixed position, and this will necessitate the mode of feeding the carbons to be effected by a powerful spring.

Of course the main force tending to bring the carbons together must not be allowed to bring them too close. The most usual method is to cause the shunt current, by some electro-mechanical contrivance, to clock the action of the "feed," except when the distance between the carbon points becomes too great. When this happens the resistance opposed by the arc of light to the current is increased; so that in most of the artificial arrangements which have been devised for effectuating this, which is an instrumental measuring of differences of resistance. Thus, when the resistance of the arc becomes too great an electrical mechanism is brought into action which releases the "feeding" mechanism and causes the carbons to approach each other until the resistance is again adjusted, when the "feed" is again checked.

The principle of this has been applied in a good arc lamp as follows:—The shunt current is made to pass through a small change in the resistance of the arc will allow the "feed" to act, and so to the moment of the approach. The adjustment is gained by making the moving parts as light as possible and by employing the most delicate electric contrivance for checking and regulating the "feed." One of the most beautiful results designed to fulfil this condition has been furnished by Sir Charles Bright, in which the delicate apparatus known in telegraphy as a relay is used to determine when the "feed" shall be given. But during the past few years inventors have devoted most of their attention to preventing the overfeeding, which produces a blazing noise, often accompanied by sputtering and flickering. In the Brush and many other lamps this is effected by connecting the moving parts of the mechanism with a piston which falls in a tube full of gravelene. In the Jaspar, Gulcher, and other lamps the glycerine is replaced by mercury. In the arc form of Siemens lamp the "feed" is checked at each beat of a pendulum, and is allowed to continue only if it is required. In the Gramme lamp it is similarly checked by a spur wheel at the passage of each tooth. In the Crompton lamp a light centrifugal governor performs the same office. In the Pilsen lamp and some others an overfeed produces opposing electrical forces which cause the carbons to recede again to their proper distance. This is the principle for the great steadiness of this form of lamp when it is not shaken. If by the irregular action of the steam engine the current is increased, the resistance of the arc diminishes and a sputtering would tend to set in; but no further separation of the carbons was possible. Several arc lamps are used with alternate instead of continuous currents; but in this case there is some loss when the current has to be conveyed to any distance. There is one lamp, however, of this class, the Gerard lamp, which has lately been perfected, and is so remarkable for its steadiness as to attain that it deserves a passing mention.

In some kinds of lamp the feed is given only at intervals. This was the case with the Wallace-Farmer lamp, in which, when the arc became too long for the current to pass, the carbons were brought into contact, and then separated by the strong current thus generated. This produced a momentary blinding flash. In the Brockie lamp this is produced at intervals of about half a minute by a separate current in the place of the shunt current. The arc is never seriously lengthened, so that it is virtually a lamp with a fixed distance between the carbons, subject to a periodical flicker.

Numerous lamps have been invented in which the "feed" is regulated, so that the carbons are fixed and the arc is constant, but the distance between the carbons increases. From these lamps is very steady, and in most cases the position of the arc of light remains fixed while the carbons wear away. This is the plan adopted in the Jablochkoff lamp, which has been described, and which has been successfully used in the office of *The Times* for years. The lamps of the Wilde, Jablochkoff, and Jamin type, in which a fixed distance is maintained by having the two carbons side by side and separated by the distance required, and which, have not found much favour in this country. In the lamps of Sir Benjamin Stone, Siemens, and Joel type, in which a thin rod of carbon is kept in contact with a block of carbon or metal, and a light is given, partly by the intense heating of the point of the rod, and partly by a small arc which appears between the block and the adjacent part of the carbon rod.

There is, however, one of these lamps of a purely incandescent form which deserves special notice. The lamps soleil, or sun lamp, when exhibited at Paris, was almost universally condemned by electricians, but since then it has risen in favour, and is now in daily work in Paris and elsewhere. It consists of two short thick rods of carbon of the cheapest kind, which slide down two platinum tubes in some refractory material, so that their lower points would meet were they not separated by a block of marble, which is shaped so as to throw the light in any required direction. Over this, consisting of a thin piece of carbon, connects the platinum tubes at first. This is heated and burnt away after having heated the marble and rendered it conducting, so that the current can pass from one carbon rod to the other. Although the currents of high intensity are generally used, the light is steady and good in position, the lamp itself is very cheap, and the cost of materials consumed is insignificant.

As would be as ludicrous a task to attempt to say which is the best kind of arc light for a given purpose as to discuss the patent rights of the inventors of electric lights and machines. What has now been said will enable any one to grasp the distinctive features and merits of different kinds of lamps which may be in the form of Siemens

It is now nearly 40 years since the first attempts were made to produce an electric light by the passage of a current of electricity through a material of high resistance. Carbon was selected because it has never been fused, and probably remains in a solid state at the highest temperature to which it has been raised. (The word probably is used because some spectroscopists think otherwise.) Next, when carbon is heated in the air it combines with the oxygen and burns away. For this reason the rod or thread of carbon has been enclosed in a globe of glass from which the air is exhausted. But here a new difficulty arises, for carbon is found to contain a large quantities of gas within its pores. When the carbon is heated this gas is evolved, and partly by combination with the carbon, and it may be partly in other ways, wears away the incandescent carbon, often degrading it as a film, black lamp soon the glass globe. Ultimately the filament or carbon gives way, and the current cannot pass. By keeping the carbon at a high temperature in an electric current, and continuing to exhaust the gas which is evolved, this defect is partially avoided, but a new defect has been met with. In maintaining a perfect vacuum, for making a good connexion between the carbon thread and the metallic connexions, and for securing carbons of uniform resistance, and with many carbons. The carbon threads are generally made from some vegetable fibre in its natural state or in a manufactured condition. This raw material is then generally packed away in charcoal parts in a crucible and put into a furnace for some hours. This converts the material into a charcoal filament, upon which some makers deposit carbon by heating it with an electric current in an atmosphere of hydrocarbon until the deposit of carbon has made the resistance of the filament exactly equal to the standard. The prepared thread is then attached to its wire terminals, which are welded to some glass tubing. It is then introduced into the globe, and the air is exhausted by a mercurial pump, and the globe is hermetically sealed. The current is then passed through the filament, and the electric current is heating the filament to incandescence. This is the process in which, with modifications, is followed in the construction of nearly all incandescent lamps.

The softness of the light of these lamps, their absolute steadiness as compared with a gas light, the small degree to which they heat the air, and their non-consumption of the air by burning, the state of purity, render these lights as perfect as they could be desired. Their lasting qualities are now very good, and the question of expense has now reached a point at which general adoption on a large scale. Their cost as compared with that of gas, with equal lights, is considerable; but it must be remembered that in most cases of lighting by gas the heat evolved is considered than one lamp of 1,000-candle power. The great branch which the Crystal Palace Electrical Exhibition of last year conferred on the public was to give them a practical opportunity of seeing for the merits of the incandescent system of electric lighting, and of its suitability for domestic purposes. The extent of this system at the time of and after the Paris Exhibition was so enormous and so sudden that the display of incandescent lighting at the Crystal Palace was undoubtedly the most magnificent which has yet been seen.

The largest installation of incandescent lamps in the way of town illumination has been partially completed by the Edison Electric Lighting Company of New York. About 14 miles of street conductors have been laid, and a trial of 5,000 lamps has been made. No complete information as to the details of construction, cost, &c., has as yet reached this country, but there can be no doubt that such a valuable illuminant will be extensively used in America as a trial.

In Great Britain and Ireland companies have hitherto been hampered by rival interests. The President of the Board of Trade deserves all credit for his carrying through the Electric Lighting Bill and encouraging experiments. But he is to be regretted that many of the local authorities are averse to making use of their new powers, and the gas interests will raise many opponents at every step in the movements of electric lighting.

There has been a good deal of alarm about the free risks of electric lighting. It is very right that the risks attending every system of lighting should be guarded against, but such legislation caution must not be allowed to degenerate into panic. A very wise course has been taken by the Society of Telegraph Engineers and Electricians in appointing a committee to discuss these fire-risks, and to recommend rules and regulations for reducing them to a minimum. The most common source of danger arises from the possibility of a short circuiting. The wires leading to an incandescent lamp may be very thin, for the current passing through them is feeble, owing to the high resistance of the lamp. But if the wires, by abrasion, bad insulation, or other cause, happen to meet, the resistance of the lamp is then cut out, and a powerful current passes through the wires and heats them sufficiently to inflame any combustible substance in contact with them. The chief precautions recommended by the committee are good insulation, the employment of sufficient diameter, frequent testing for "leakage," and the use of cut-outs and the introduction of "safety fuses." These are usually made of lead wire of such a diameter that they would melt with any current arising from a short circuiting which would be dangerous. Moreover, the supervision of the work should be intrusted only to experienced and skilled electricians. The committee also recommend that the earth should form part of the conducting current, as it increases all the other risks and dangers. Of course there may be exceptional cases where this precaution may be unnecessary. Arc lamps should be provided with separate cut-outs to prevent the carbons and glowing carbon from flying about. Special care has to be taken to the gilsen of the switches, so that they cannot become overheated, nor give rise to a measure gas.

But there are also dangers to life, and several deaths have arisen from the employment of dynamo machines of very high potential which have been used for medical purposes. The committee will be accused by some of being over-cautious. They recommend that a current of electricity of greater than this would ever be used in the present state of electric lighting. The amount of electricity passed would not seriously injure a man, but the danger would be that the respiratory muscles would be interrupted by a lamp going out while his body still completes the circuit. In that case he gets the full force of the "extra current" momentarily, and the muscles of respiration are paralysed. This machine, and this may lead to a most serious and dangerous accident. There is another recommendation which is most wise, but which will affect the interests of many. It is suggested that "the lanterns and all parts which are to be handled should be insulated from the ground."

A great deal of interest has been taken in accumulators, or storage batteries, in the past year. Most people will be aware that the quantity of working with the Faure accumulator in 1881 came to the conclusion that it was by no means perfect. Its chief defects are that the lead plates wear away, that the felt which envelops these plates becomes rotten, that the

minium or red lead which is spread upon the plates falls off, and that great supervision is required in charging and discharging the cells. It had been hoped that these accumulators might be charged at some fixed place—perhaps by the force of a waterfall—and then transported to any place where energy was wanted, and used to drive machinery by means of electrometors. The falling off of the minium proved a serious obstacle to the realisation of such hopes. To make the minium hold more firmly, round holes were made in the lead plates, and these were filled with the minium, or the minium was put upon a frame of some kind. Such accumulators are forrasting in form, but it has never been found that the most regular and efficient action is obtained with plain plates, and any depressions or holes in the plate induce irregular action. The Faure-Sellon-Volckmar accumulator is said to be free from the old objections. Other materials have been used instead of minium, and lithargre promised good results. In all these cases the advantage gained over the old Plantí accumulatory was that, by putting on a layer of an oxide of lead, the process of "forming" was much shortened. This process consists in passing a current through the secondary battery first in one direction, then in the other, reversing and repeating it at times, and treating it in this way for months, after the plates have been put into the cells. It was a laborious and ex-tensive operation, but the result was, if anything, more satisfactory than in any of the forms in which a salt of lead is laid on the lead plate, directly at. Planté has succeeded in rendering the place of his lead plates slightly porous by treatment with dilute sulphuric acid. This is found to facilitate the "formation" of the plates very much indeed, and the porosity is also produced (in lead in a finely divided state) by deposition from the solution of lead salts or other means; and by compressing the powder into a compact mass they have obtained sheets of very porous lead. The rapidity with which secondary batteries made of this material can be "formed" is remarkable, and those who have made experiments on these plates find them to be superior to any others. It seems, then, that after all there is no decided merit which was raised above the Faure battery, we are likely to return eventually to a form which resembles a Planté accumulator of a much greater extent. It is satisfactory to know that the economy of secondary batteries continues to be carefully studied by Dr. Gladstone and Sir. Trike, and also by Professor Hodge. Their chief result is that the action observed in these secondary batteries is largely influenced by the sulphate of lead formed by the reaction of sulphuric acid in the cell. These researches promise to help greatly in the future development of the invention.

It may be confidently said that so soon as a practically perfect accumulator is devised its applications will be very numerous. The current which is required from it is much more steady than that which is obtained from a dynamo machine, so that a light obtained therefrom is more steady, and incandescent lamps are more liable to be injured by sudden changes of temperature. Moreover, when a number of these accumulators are placed between the two wires going from a dynamo machine to a system of incandescent lamps, they act as a regulator on the current from the dynamo machine, much in the same way as a flywheel acts as a regulator on a steam engine. In any extensive system of electric illumination by incandescent lamps it is probable that stores of accumulators in different districts will be fed by the machinery from a central station, and that each of these will feed its district with the electricity required for illumination. At present accumulators require too much care and attention for their introduction into each private house.

In the course of the correspondence from the Paris Exhibition published in *The Times* for 1880, it was stated that the prevalent feeling among electricians was that the problem of electric lighting was solved, and only awaited further development, and that in a few months the greatest advance might be expected to be in the applications of electricity to motive power. A great many experiments have now been made in that direction, and although there is not yet any great advance to chronicle, there is no doubt that these attempts will give electricians much useful information.

It is to be hoped that before very long electricity will be used so much for electric lighting that it will be laid on, like water or gas, through subterreats in our principal towns. When that is done there is no doubt that this constant motive power will be largely used. But at present the cost and inconvenience of generating electricity on a small scale prevent its general adoption. Motors for converting the electric current into work have been invented, and they do not leave much room for improvement. There is one such invention in this branch of the science. The only striking novelty in the invention of Dr. Werner Siemens, of Berlin. He causes a metal ring to rotate, supported at its outside by two sets of three rollers, one set being bevelled and working in a groove on the ring, and the other set working resembles a Gramme ring in form, but only three-quarters of it is wound from the insulating material is of brass. This ring revolves inside coils of insulated wire, like the coils on the ring of a Gramme machine. But in this machine the coils are fixed. The iron ring of the ring is magnetised by a current passed through the coils, and at the same time by the magnetism from ring is induced further into the coils, just as an iron rod is sucked into a coil of wire through which a current is passing. As the ring turns round the current is passed successively through the different coils by means of an ingenious and novel commutator. Of course the reverse machine action might be used to generate electricity. There is no doubt that theoretically this is a very perfect form of motor, but there are great difficulties in the way of making it a really practical machine. Only a model has as yet been made, and although of most beautiful construction, it is said to be one that great difficulties must be met before it can be considered perfect.

In all attempts to utilise electricity as a motive power, the idea has been to generate the electricity at a fixed station, probably a waterfall, where the source of power costs nothing, and to send the current by wires to the place where the power is required, or to use water-power to charge secondary batteries. Whether the railway train or a fixed machine, the current is then passed through an electric motor, which turns round and drives the machinery.

The most interesting part of the Electrical Exhibition at Munich last autumn was that which dealt with the applications of electricity as a motive power. At a distance of two and a half miles from the Glass Palace there is a locomotive factory at Hirschau. At these works the power is obtained from Fontaine or Jonval turbines driven by a large volume of water with a small fall. About 500-horse power are thus made available. Mr. Schuckert, of Nuremberg, utilised one of these turbines to drive one of his large-sized dynamos, and conveyed the current by thick copper wires to the exhibition. There it was utilised in the day time to drive agricultural machinery by means of a second dynamo of smaller size, and at night to light up 32 Pilsen lamps. About one-eighth of the current was used up by the resistance of the conductors.

At the same time, M. Marcel Deprez made use of the ordinary iron telegraph wire from Munich to Miesbach, a distance of 561 miles, to transmit the power generated by a steam engine at the latter place, and utilise it in the exhibition to pump water. Of course, to do this effectively, it was necessary to wind the dynamos with very fine wire, so as to produce a high electromotive force. The former many difficulties to contend with, but he certainly produced half-a-horse power at Munich, and this sometimes found that there was a return of 58·0 per cent., while they added that occasionally the result was even better. These experiments are very interesting and instructive, and any settlements by the same eminent electrician on a much larger scale are now being made. The latest experiments have been made by him at the workshops of the Chemin de Fer du Nord. The total length of the line was 105 miles, ordinary iron telegraph wire being used as the conductor. Such a system would connect two stations 52 miles apart. In the latest of these experiments it is stated that 45-horse power was delivered by a motor; 10-horse power being used to drive the machine which generated the electricity. Thus it appears that when giving off 45-horse power the efficiency of the combination of machines was 40 per cent. These experiments are being carried out under the direction of a committee appointed by the Academy of Sciences. It is probable that the French Government will assist in developing a knowledge of the mechanics of electricity in the same way as they did with the mechanics of steam when they assisted Regnault to carry out his splendid researches on heat. It is to be regretted that so little has been done in this country in this very promising field. Science is even now in a position to utilise the forces of nature more on the pit mouth, and convey the energy by electricity.

Some progress has lately been made with electric railways. The first was made by the late Lord Dunraven of Siemens and Halske, for the Berlin Exhibition in 1879, where a few small carriages were driven round a circular tramway about 50 yards diameter, the gauge being 0·70 of a metre. In April, 1881, the same firm constructed the Lichterfelde and Berlin electric railway, which is three kilometres long. One of the carriages of this line was shown at the Paris Exhibition last year. The current is passed through the rails, which are insulated. It is then taken up by the wheels and so passed through the motor. The motor turns at a very rapid rate, but it is geared to the wheels of the carriage by belting of wire rope, which reduces the speed of revolution so rapidly as to maintain appearances of an ordinary tramway car, and the machinery is invisible. It was expected that some might prove troublesome in such a system, where the current is passed through the rails, but during winter of 1881-2 was so mild as to be no test of this. At the Paris Electrical Exhibition a somewhat similar car was used, but Messrs. Siemens were not allowed to utilise the rails, as though as rails, on account of the danger to horses, &c.; horse they were obliged to carry conductors consisting of split tubes on telegraph poles, and a small current was distributed to each train which made electrical contact with the motor on the car. Another electrical railway has now been completed by the same firm, between Charlottenburg and Spandauer Bock, a distance of two miles, and carriages is used, as at Paris. This line is 3¼ kilometres long. Two-and-a-half kilogrammes are loved, but this line is specially interesting from the fact that a whole kilometre is on the very considerable incline of 1 in 20. Messrs. Siemens have also applied the same principles to haulage in mines. A small electrical locomotive is used in a mine near Dresden with a driver eight metres loaded with coal. In general experience of Messrs. Siemens has gone to show that it is more satisfactory to use overhead wires than the rails as conductors, and that by using a greater electromotive force may be used; and also that rail conductors should never be placed upon the level of the ground, but that elevated railways alone are permissible on this principle.

The electrical railways spoken of in the last paragraph are all *fairs accomplis*. But besides these completed railways there are many such schemes. Special attention may be drawn to the line which is being constructed at Portrush and the Giant's Causeway, in the north of Ireland. This railway is to be worked by electricity. It is intended to drive the cars by means of turbines, which will be driven by water obtained from the waterfalls which abound in the district. These will drive turbines which will be made to generate the current. The electricity is to be conveyed along the iron head, the return current passing through the rails and the earth. It is also proposed to use accumulators, which will be charged by the machines on the locomotive while going down hill.

Mr. Edison is also constructing an experimental line in North Park. But the information which has reached this country through his own agents is of so fragmentary a character that it is impossible to give any opinion upon his scheme, nor has anything been done as yet to add to the engineer's knowledge of the conditions of the problem. Mr. Volkem's representatives in England state that the line is to be eight miles long. He is stated to believe that the only weight (and that small) will go at 40 miles an hour; that the loss in the machines will be only 10 per cent., but that he allows for a loss through leakage of the insulators of 50 per cent., and that the cost will be 33 per cent. cheaper than a steam locomotive. But as he is said to assume that a locomotive costs 6d. per horse-power per hour, it is clear that no opinion can be formed on the subject at present. The electromotive force is stated to be only 110 volts, which will involve the use of large and expensive conductors.

There is no doubt that so long as trains are driven by electrical connection with the electricity generated by steam power, no economy will be gained. This was distinctly stated by Siemens, at the last meeting of the British Association, by the president. Address. No attempt has as yet been made to apply the electrical motive power to any carriage or truck on a train. The advantages of such a system are numerous. The weight of engines would be permissible; a train would reach its full speed after stopping as rapidly as an automatic brake now stops it; and the wear and tear of the lines and rolling stock would be considerably diminished. From this point of view it is not impossible that electricity may be successfully employed through the intermediary of electrical action in some cases.

Messrs. Coulard and Gibbs have lately introduced a novel plan by means of which a small kind of current of high or low tension can be derived by each different consumer of a current from the main circuit. They generate electricity with an alternating current machine, and supply a number of people on a single circuit. Each consumer has a convivence on his premises by means of which he can carry off the current he requires, whether for transformation into heat, lighting or for motive power. This contrivance consists of a coil of wire connected with the main circuit, round which there is another coil of wire, thick or thin, large or small, according to the current required. In the main circuit another coil is quite unconnected with the main circuit, but its two ends are connected with the lamps, &c., which require a supply of electricity. The alternating current in the main circuit induces currents in the secondary coil the character of which depends upon the way in which the coils are wound. The loss by this conversion is slight, and than would have been expected *a priori*.

In the construction of dynamo machines there is no very important improvement to chronicle. Numbers of them have been invented, but these which have any prospect of success are generally

TO THE EDITOR OF THE TIMES.

SIR,—The very interesting article on this subject which appears in *The Times* of the 23rd inst. fully explains the comparative views, from which to base the matter before you from another point of view. Practically all the previous orders are still in force, but for greater certainty I will deal with the Chelsea order of the Brush Company.

The company propose for their area the whole parish of Chelsea. They suggest for the district you describe as the area (district "A") the Duke of Fellowes-row, Sloane-street, King's-road, Oakley-street, and the Thames Embankment; and they suggest that they will spend on the parish £14,000 in the first thing (as regards new mains), and leave there it rests. The parish gives up itself to the company, but the company give nothing in return. The company *need* not spend one penny, and yet they will have the parish in occupation with for two years. They may not sell or underlet by leave of the Board of Trade without any notice to us and without our consent. Supposing the company is serious in proposing to do the work, surely they should be forced to spend the £14,000, or give security that they will do so.

If a lighting centre is ever formed for this district the company may charge at their discretion by meter (when one is found accurate), by unit, energy, quantity, number of lamps, or quarterly rental. Did it ever occur before that a public body had the choice of charging in so many different ways? And is it reasonable that they and not the public should have that choice? The Act of Parliament says nothing about closing for two hours or on a Sunday. This power might cause great inconvenience to the public. The Act of Parliament says the wires should not be overload. The company take the power to go over-load. Twenty-one years was decided to be a reasonable limitation about. I may add the company have the right to say "We are governed by the Act of Parliament, "If so, why not put in 31 years? Clauses 5 and 4 of the Act, read together, show that the Board of Trade have no power to limit. This order takes away the vestry's power and gives it to the company, without inquiring why or how. Conditions or something the vestry at all.

To the penalty for failure of supply is 40*s.*, but at the end of clause 50 the following words are inserted:—

"Provided always that the undertakers shall not be held to be liable to penalties under this or any of the preceding clauses of this Act for any failure to supply or any interruption to the same beyond the undertakers' control, or could not have been prevented by the exercise of reasonable care and skill.

"50. The undertakers shall not be deemed to have committed a default in respect of their supply unless such default shall, from the frequency of its recurrence on the part of the undertakers, be evidence of inefficiency in the undertakers' staff or plant."

And having got over these quicksands the Board of Trade has power only to relieve from penalties.

I venture to say that it would be just as well to leave out the penalties altogether as to put in words which are so full of loopholes. Clause 49 provides that the undertaker shall be present at such testing in this department, which is known by the company that we will test at a given time, when it may be presumed the branch will be exhaustively tested, and not for three months after that the company may go on saying that they are under the direction of Mr. Gordon, Mr. Crompton, chairman of the company, and Mr. Pamphilon, of the Post Office, for the purpose of witnessing the effect produced. This seemed to be all that could be desired, the room to all intents and purposes being a theatre. But a great improvement in the new system of lights is that it has done away with the coal gas in which the room was previously lighted, 16 of the Brush lamps, each equal to 2000 candles, being substituted.

The temperature has been reduced by ten degrees, and the reading of addresses by the employés much facilitated. Indeed, the whole feeling of the latter in regard to the matter is greatly in favour of the new lighting apparatus. The electric machine is driven by a double-cylinder engine of 14 horse-power, supplied with steam from one of the boilers. The experiment, on the whole, seems to have given complete satisfaction, the authorities at the Post Office being greatly pleased with the result of this innovation on the old system of lighting their premises.

Sir,—I have observed the communication from a correspondent in *The Times* of the 23rd inst. on the subject of the manner in which the electric companies propose to manipulate London and several provincial towns by obtaining Provisional Orders from the Board of Trade which will have the effect of enabling private companies to take up the supply of the public thoroughfares and private houses. There is at present no power compelling anything to obtain powers, to the exclusion of others, for lighting the principal streets of London, and it would be a very ill day for the public which should understand the nature of some of the powers which the companies seek to obtain. The Order contains clauses which are contrary to the provisions of the Electric Lighting Act, 1882, and the necessary clauses referred to in the Act are omitted; for instance, it is enacted that no wires shall be fixed overhead without the consent of the local authority, but the undertakers propose to run wires under, over, and along any streets within the area of supply without obtaining any such consent. The Electric Lighting Act states that consumers shall have the right to sheet electricity for all purposes; but the Orders seek to qualify this by stating that the purposes for which the supply of electricity is intended are private and public lighting only. The undertakers offer to give the supply, either directly by the direct system or by the meter system, but they fail to give any indication of the difference in the proposed mode of supply.

The undertakers propose to place house connections, motors and other apparatus under the public ways opened for any house, and to keep the same connected with the supply, but the consent of those local authorities who are the trustees otherwise at the same time of short dividing spaces of streets is not required. The price at which the gas is supplied is regulated by schedules referred to in the Orders, and it is possible under these clauses that certain portions of the scheduled areas to be left without the electric supply, and that the gas companies, which alone are able to do so cheaply to all of the districts, may cut off the supply at reasonable profit to themselves.

Again, it is sought that the notice of supply should be settled by agreement, or, in case of difference, by arbitration, but there are neither provisions for fixing the price over one area nor that the maximum price stated in the Orders shall be the same for all areas. The Electric Lighting Act enacts that every person within an area shall be entitled to a supply upon the same terms. The Provisional Orders which have been obtained necessarily contain a contract to continue to receive and pay for the supply of electricity for a period of at least two years, and that the amount payable shall not be less than 20 per cent. per annum on the capital expended. The local authorities are also by an illusory proviso allowed to compel by way of security, there being no provisions in the Act requiring security, to enter into any such contract or to give any security. This, it will be remembered, has been found formidable obstacle to the Post Office in the matter of contracts for electric lighting of their premises, and which they have had to overcome. But if the undertakers think that it is even worth while to enter into the question, why should they not? Under some of the clauses the undertakers may, after the expiration of seven years, have their undertaking sold to their bonuses and premises, be released from their obligations, and the whole of the undertaking be sold to the local authority upon such terms. The storage of electricity by consumers during the hours of supply is sought to be forbidden, and the supply of electricity by consumers may be altogether without their consent.

These are some of the extraordinary powers sought to be obtained by the undertakers. The local authorities and persons likely to become customers to oppose these being granted by the Board of Trade, and the Legislature and the standing orders of Parliament may desire to have the matter referred to the Board of Trade tentatively.

I am, Sir, your obedient servant,

GEORGE L. WIGGIN.

Ancel-court, E.C., Jan. 26.

46 Cannon-street, E.C., Jan. 26, 1883.

SIR,—In reply to your letter of this day's date, I beg to say that I have no objection to your publishing my letter of the 23rd inst. in the columns of *The Times*.

I am, Sir, your obedient servant,

OLAF MOSSOP.

GEORGE L. WIGGIN, Esq.

more modifications at the outer machines, and this article still maintains rank of efficiency against all the new comers. A very general feeling has prevailed among users that the directness in which machines will be improved will be in making them larger, so that, instead of revolving from 1,000 to 1,200 times a minute, as many do, the speed shall be reduced to between 600 and 700 a minute. In all the way the belting may be done away with, and the dynamos attached directly to the steam engine. The rapid-rotation engines which have sometimes been used are generally condemned by experienced engineers. Mr. Edison has completed machines of this type, the last of which was shown at the Paris Exhibition, and described in these columns. It was constructed to supply the current for 1,000 of the incandescent lamps. It has been successful in giving good results, and it is very much less dangerous than many of smaller dimensions which have largely used.

But the past year has seen the completion of the largest dynamo machine which has yet been constructed. It is designed by Mr. J. E. H. Gordon, and was built by the Telegraph Construction and Maintenance Company at their works at Greenwich. It can generate a current capable of supplying from 5,000 to 7,000 of Swan's 20-candle incandescent lamps; but the engine power hitherto supplied has been sufficient for only 1,500. It is an alternate-current machine, founded upon well-known principles, but containing important novelties and improvements. It has a workmanlike appearance, and mechanically its construction is excellent. The revolving inclosed weighs seven tons, and is 8ft. 6in. in diameter. The wheel carries the inducing magnets. The coils in which the available current is generated are fixed in position. Mr. Gordon contemplates making still larger machines on the same plan, but it is to be congratulated on having already made an immense step in the right direction. The only objection to this form of machine are those common to all alternate-current machines.

Another machine of the same class has been lately noticed in *The Times*. It is the Ferranti-Thomson dynamo. Its armature is made of copper ribbon wound in a novel manner, and contains no iron. It is designed so that the magnets of the one very close together, and the armature revolving between them is very light, and can be driven at great speed. There is no new scientific principle involved, but it is the lightest machine which has been designed to do so much. The one which was publicly exhibited weighed about 1,000lb., including the exciting machine. It supplied 200 of Swan's 20-candle lamps.

Mr. Crompton has been busy in perfecting a dynamo engine upon the same lines, so that it shall feed a large or small number of incandescent lamps equally well, on a principle which has been explained in several people. In ordinary dynamos the current is made to go round the magnets of the machine before it is led away to the lamps. In this case we find that if some of the lamps are put out the others become too bright. In other dynamos the current which supplies the magnets is taken as a branch from the wires which lead to the lamps. In this case, we sometimes find that if some of the lamps be put out the others grow dimmer. This was first noticed by Dr. Siemens. By the ingenious expedient of taking part of the current for the magnets from the circuit of the lamps, and not from a branch circuit, it is found that, when some of the lamps are put out, the others become rather brighter nor dimmer.

Although no startling improvement has been made of late in the principles of construction of dynamos, much has been done in studying their capabilities. A large number of experiments have been made by scientific men in obtain information on the different electrical and magnetical phenomena. The result of this is that a competent electrician is now able to draw out a specification for the construction of a dynamo machine which shall give the results required, on however large a scale, for any proposed installation, with as great accuracy as a mechanical engineer would design a steam engine for a special purpose. Hitherto the duties of the various parts of machines have been gradually arrived at by a system of "trial and error," which in future will not be done by strict calculation. The era of accurate measurements is now according to that of vague statements. This is largely due to the introduction of a universal system of measurement, founded upon the original suggestions of the British Association. It is a matter for congratulation that our engineer, Sir William Thomson, the late Professor Clerk Maxwell, and others recognised so long ago the necessity for a universal system of measurement, so as to have prepared the way so completely for the practical workers in electrical science, who otherwise would have been much impeded without such a system. The most important function of the Conference at which met at Paris in the year before last was to sanction such a system of measurement and nomenclature. At this date, a year and a half later, there are few workmen in charge of electric lighting who have not a good notion of the amounts expressed by a volt, an ampère, or an ohm; and the watt, or measure of work, will soon be as universally accepted. The electrical movement last that they owe a debt of gratitude to M. Cochery, the French Minister of Telegraphs, for having recognised the importance of these functions which such a Congress could effect, and for having so organised it that the decisions have so rapidly and so universally been accepted.

MAY 13, 1881.

IRON.

THE BRUSH LIGHT.—The directors of the Anglo-American Brush Electric Light Corporation find that the wires through their pipes under the streets of the City have not been sufficiently insulated, the gutta-percha covering having been steadily perishing away.

Therefore, ordered the present wires to be taken out of the pipes, and other wires, with thicker coverings, substituted by the Gravesend workmen. This will be done within a few days. The engines, dynamo-machines, and boilers are working perfectly, but the defect of insulation above referred to has been manifested in several places, and this will, with a view to the satisfactory settlement, to the above decision.

THE ELECTRIC LIGHT AT THE GENERAL POST OFFICE.—The experiments with the electric light which have lately been made in the basement of the Post Office have extended to that portion of the Post Office devoted to the sorting out of newspapers and circulars preparatory to transmission by the various destinations. The room used for this purpose is extremely large, so may be imagined when it is stated that from about 200 to 250 persons are daily at work in it. The electric light used in this department, which is known by the name of the American Brush Electric Light Company, being in full working order, a visit was paid to the Post Office on Tuesday evening by a number of persons interested in the question, under the direction of Mr. Scudamore, the superintendent of the company, and Mr. Pamphilon, of the Post Office, for the purpose of witnessing the effect produced. This seemed to be all that could be desired, the room to all intents and purposes being a theatre. But a great improvement in the new system of lights is that it has done away with the coal gas in which the room was previously lighted, 16 of the Brush lamps, each equal to 2000 candles, being substituted.

The temperature has been reduced by ten degrees, and the reading of addresses by the employés much facilitated. Indeed, the whole feeling of the latter in regard to the matter is greatly in favour of the new lighting apparatus. The electric machine is driven by a double-cylinder engine of 14 horse-power, supplied with steam from one of the boilers. The experiment, on the whole, seems to have given complete satisfaction, the authorities at the Post Office being greatly pleased with the result of this innovation on the old system of lighting their premises.

GLORY GALORE!

The Queen City of the Northwest Now Radiant Twenty-Four Hours a Day.

Elgin Confessedly the Best-Lighted City on the Globe.

The Inaugural Light—The Banquet—The Toasts—The Story.

The Favorable Night.

Saturday was a day of expectation. The word that passed from mouth to mouth about the light the night before seen by but few, and the reports of its grandness had aroused the curiosity of nearly everybody. There was a general said about the coming illumination and much speculation occasioned in consequence. So, when the announcement was made that it would probably start at 7 o'clock and splendid centered on that hour; yet the shades of evening had no sooner set in than many a glance was directed upward and many an exclamation was heard as to the probabilities of realization of hopes or of disappointment. When the hour of sunset arrived the streets were filled with gazers waiting for the sudden flash; and in the more remote parts of town not a few had left their houses and sauntering in the yard or standing at the gate had their optics strained for the bright sight of the first new light. "There it is," and sundry ejaculations were heard from time to time, emanating from fun loving folks who enjoyed seeing the sudden start made by their neighbors at the announcement struck their fears; but it was not to be. Mrs. Miss Anna Bowman, daughter of Mr. Geo. A. Bowen, moved the lever at the dynamo connecting with the circuit. The wire pulsated with the current and the beautiful meteor or ellgence on seven towers instantaneously transformed darkness into moonlight. Perhaps there were present fifty persons, in and out of Richards' mill, where the dynamos are located, who witnessed the simple yet important event and transferred their vision as the switch moved, from it to the lights. The delay from the original intention was caused by the incompletion of arrangements on the tower last erected, in West Elgin. So soon as all was ready the electrician, Mr. Sloat, gave the word and pressed the thing was done.

A stroll about town by the writer was at once indulged in and opinions on every hand were heard. In scarcely an instance were they of a derogatory nature. Two of the lamps on the fountain tower did not seem to work entirely well, but the others there did nobly, and the light flooded the business streets and extended in all directions. The fronts of the blocks were brightened by the bale; the ledge stole across the black river and made silvery pathways; the very air seemed warmed by the gentle influence; and when one stood where he could see all the towers at a distance, the lights appeared merged into one large ball on such structure and to stand like sentinels at convenient intervals watching over the destinies of a busy city. It was a magnificent picture.

At 8:30 three conveyances started from the court house. The first contained Mr. Bowen, Mayor Barclay, Alderman Welsby, ex-Mayor Bosworth, Mr. Bailey, of the Vandepeer company, and other representatives of the daily press. The others carried members of the city council and a visitor or two. The object of the expedition was to view the lights by making a circuit of the city and to spy out the dark places if any there were. The route was up Douglas avenue to Lovell street, thence to Spring, down Spring to a turn which took the party over to Dundee street, thence to Park, Park to Gifford, Gifford to DuPage, DuPage to Channing, Channing to Villa, thence to Liberty, Sherman avenue, St. Charles street, Villa street, Chicago street, and across to West Elgin. All along the line the Illumination was all that could be desired. Beneath the towers and for several blocks it was as light as a full moon could have made it. In other places it was light enough to see the time by a watch, and, to keep out of holes in sidewalks and ditches in the street. What more could be wanted? The cities of inspecting the work of the superintendent of streets by night was entertained as novel; yet it was done. Elgin is the first city to adopt the Vandepoele light on towers, and the company's men were highly elated. Words cannot express the beauty of the spectacle about the meadow, which lights appeared to about the best advantage of any on the east side. It will not be necessary hereafter when lawn boards are to assist to wait for the moon, or use lanterns. After a tour of the west side, which was, if anything, better lighted than the east side, the gazers repaired to the Nolting, in whose office by the time 10 o'clock arrived were over a hundred gentlemen, invited by Mr. Bowen to his banquet. "Then they were, all discussing the subject of subjects; earnestly, candidly, thinkingly; lawyers, doctors, professors, journalists and the universal opinion was "success". Men who had sneered at the project; who had ridiculed this or that part of the accomplishment; who had condemned as foolishness any movement by the council looking to a better light than gas all were there, and they were converted. "If to-night is a sample," said they, "give us the whole package. The light this evening is not as strong as last night's, but then it was cloudy and the effect was more brilliant, and the power at the generator was greater than now, not having so many lights to create. We are content."

The Banquet.

At 10:30 o'clock Mr. Bowen threw open the doors of the dining room and invited the guests of the evening to enter. One long table and ten or fifteen smaller ones were beautifully spread with appetizing viands in readiness for the beginning of gustatory movements. The brilliant rays from the large chandelier, suspended from the ceiling center, and from the other burners gave the place a brightness only exceeded by the happiness that was everywhere noticeable. The guests seated themselves as suited their fancy. The following list of those who were present, as complete as it can be made, is a better evidence of the character of the representation than words can tell. Around the tables were Ex-Mayor Bowen, Mayor Barclay, Aldermen Coffee, Fllen, Mann, Towne, Joslyn, Welsby, Bolles, Wood, Hawkins; ex-Mayors G P Lord, W L Pease, E O Lovell, E F Hewes, F S Bosworth, Dr. J Duffy, G W Beswick, Geo D Sherman, R P McGilney, ex-Ald Wall, ex-Ald Sherman, Ald Chisholm, F H Goodman, F H Taylor, C F Kimball, A H Lowrie, P E Allen, F L Allen, G W Raymond, W S Doherty, Byron Clark, Dan Barker, C S Chisholm, F W Warren, J M Kimball, Ed Springer, Jos X Gardner, Mr. Buchanan, Dr. Clark, M C Town, Alfred Bosworth, Frank Crosby, Geo E Bowen, Will O'Hatra, E J O'Hatra, S E Weld, Wm Hart, John B Newman, G E Gregory, D J Chamberlain, Phil Preller, Jos Miller, Geo M Peck, Mr Bailey, secretary, and R J Hamilton, agent, of the Vandepoele Electric Light company, Chicago; Capt Smullen, Col J S Wilcox, Clay Clark Sylin, Thos Field, V E Lovell, Carlos Smith, E D Waldron, Will Elliott, Geo Sinnier, ex-Ald Jackson, J Fisher, ex-Ald Jencks, Will Tobey, G E Lightner, Monroe Wallace, Will Hemmingway, Chas Pratt, Jr., H F Woodward, Ed Starr, Alex Simmons, Geo Van Dyke, S A Kilbourne, Wm Creighton, C Rasmussen, S J Gifford, W J Kline, Chas Wallace, W T Watt, John Newman, J C Russell, D B Sherwood, E Byington, Frank Kramer, Ira Brown, J K La Baron, H H Denison, Prof. Schmitz, A M Lewis, George Sherman, Mr. Sloat Mr Anderson, Gus Pendergast, Will Hubbard, Malcolm McDowell, of Chicago, the European quartet—A. P. Kelsey, W G Merrihew, L Hutchison, W C Torry.

The Enterpeans opened the "exercises" with a song, which paved the way for a discussion of the good things set before the company, and the clear of plates and knives and forks told that the luncheon was being attacked with vigor. The spread was a fine one, the company were electrified with the spirit of the occasion, and the feast of reason and flow of soul, or words to that effect, followed this first act of the program naturally and easily. The banquet was a brilliant affair. The host of the evening, Mr. Bowen, was particularly felicitous in his informal post offerings, and almost, by his pat expressions, placed words in the mouths of those called upon to respond. For two hours the banquet table was merry and the replies were listened to with unflagging interest, and when the hour of separation drew nigh the wit was as fresh and the ear as eager to hear as at the start. As an entertaining affair it was a success, and never, we believe, was he in better mood than at this time, when, surrounded by an assemblage committed in favor of the light for whose success he has long and earnestly labored, his versatility knew no bounds and his enthusiasm was at its height. We wish it were within our power to give verbatim the toasts and responses. No abbreviated report is best under the most circumstances, but under the present circumstances it would be simply cruel. Many of them sparkled with wit and shone with sound sense, and all were characterized by the utmost thought of progress, with the sincerest light pointing the way. The quaint saying, at intervals, was excellent, and the brief speeches were dispersed for hearty laughter and prolonged applause.

It was 11:30 ere the pressure of the inner man told that he was satisfied, and after a song by the quartet Mr. Bowen arose and thanked the company for their presence. It seemed an event worthy of commemoration and the gathering was evidenced good will felt by all towards each other. He spoke of the subject, uppermost in the minds of all present, and said that he believed Elgin in the best lighted city on the face of the earth. The remarks abounded in pleasantness and he congratulated the council on the display of wisdom in selecting the electric light for Elgin. He would not detain the company by extended remarks, but would like to hear from all. He spoke of our famous city, and said he expected great things of electricity. A Rasselan has invented a watch with two wheels that runs by electricity, and he believed that that power could be made to do almost anything except wash dishes. He proposed as a sentiment "The city of Elgin: May she always be well lighted, well watered, and well paved," and called upon Mayor Barclay to respond.

"Mr. President, gentlemen and fellow citizens of the greatest city in the world," he began, and then he went on to congratulatory remarks about the success of our first experiment in electric lighting. He hoped the Russian would not be so successful as to undermine our prosperity and take from us what we enjoy. The speaker had been conservative in the electric matter and though he had tried to imagine the light would succeed he was careful to keep within bounds. The light is abundantly satisfactory, and he believed in saying so he represented the feelings of Elgin's people. It would pave the way to further improvements in the city.

"What's the matter," a hurriedly written original song by A. P. Kelsey was sung by the quartet. It was as follows:

See the people turning out, what's, what's the matter!
What's all the noise about, what's, what's the matter!
"What's the news?" is all you hear—
Timid people seem to fear
Some calamity is near—what's, what's the matter?

Does it, Bowen has come to town, that's what's the matter!
And placed Electric Towers around, that's what's the matter!
We now see right turned into day,
And also hear the people say
"Other lights must not give way"—that's what's the matter.

With this light so bright and clear, that's what's the matter,
Man or woman need not fear, that's what's the matter.
"That bogie or bunnyers will waylay,
For they choose darkness, not the day
Their deeds of derility to play, that's what's the matter.

Our city fathers, now to you, that's what's the matter,
You've always been just men and true, that's what's the matter.
When you decide upon this plan,
And act and wisely, every man,
And the people by you will stand, that's what's the matter.

Mr. Bowen's wish that the Elgin electric lights may always shed as beautiful effulgence as to-night was responded to by Frank Crosby, in the liberal speech of the evening. These are timid vantages, he said, about the business, and he was a sufferer. His boy and he are in the Plymouth Rock business. After the electric light flashed over the city he found a hen on the nest, thinking it was day time a few times time to lay. It was all very well for his hearers to laugh, but what is going to become of his hens? To be sure they would lay two eggs a day for a while, but then their constitution and by laws would be ruined and the trade stopped. As a Plymouth Rock man he was opposed to the electric light system. We must not take on too many airs and believe that at home had seven hills we must have just seven towers. If he has to sacrifice his Plymouth Rocks he would as lief do it to eleven or nine towers as to seven.

The toast maker suggested that as we lived in a great state it would be appropriate to hear from one of its representatives, Dr. Kilbourne. The doctor said he thought it was cruel in Mr. Bowen to call upon him, as he wished to say that he was much pleased with the light. On leaving the hospital in the evening he was astonished at the beauty of the illumination. The ultimate success of the system of lighting was assured.

Alds. Towne council had taken some steps in the lighting by electricity ex-Mayor Bosworth was asked to say something. He protested that he was no speaker, but said he was well pleased with the outcome of the experiment.

Dr. Tefft next spoke, in response to the sentiment, remarks that the Seattle society was appealed to when we want to be enlightened. The doctor told of the many changes that have taken place since he came here forty-eight years ago. Then tallow candles and dips were in use. In 1851 we organized a city of 2,000 inhabitants and our interest has been onward and upward. He was glad to see the step that had been taken. He would pay his assessment as his share of taxes for such improvements as the electric light.

Hon. G. P. Lord was next called upon. He was not, he said, in the Plymouth Rock business, and was not afraid that his Jersey cows would be milked to death by the new light. He congratulated the city. To-night we have the best light of any city in the United States.

Aldermen Welsby, as one who had labored earnestly for the light, was called to say a few words. He arose and said he thought he had talked enough in the past two years to excuse him from further speaking. He would be pleased to hear from Mayor Barclay.

Mayor hereby put in a few kindly words for Ald. Welsby, saying that to him as much as to anybody do we owe for the electric light.

Mr. Bowen suggested that as Carpenterville was talking electricity a word or two from ex-Mayor Pease, who is so largely interested there, would be very welcome.

"I think it useful in Mr. Bowen," said he, "to call upon me as I never made a speech in my life." He was much pleased with the light, and was frightened last night when it suddenly flashed into his bedroom window and he thought there was a fire. Carpenterville will soon have the light. Dundee is growing fast, trying to outdo Elgin.

"I know all here take a delight in our schools," remarked Mr. Bowen, and as a representative of them Superintendent Kimball will be gladly listened to (Cheers).

Mr. Kimball thought the electric light was dim as compared with that by which Illumines the soul, but for which we should not have the former. We are apt to overlook the fact.

With a few words about the press as a disseminator of intelligence, and as largely aiding the peace of books, which we do not find time to read, the chairman asked Mr. Lowrie to speak. The latter was not aware, he said, that the daily press had so extended a circulation as had been intimated, but that it is no doubt it should have. Before coming to Elgin he had heard much of our city—of its condensing factory, board of trade, watch factory. The remarkable zealotry of its people had struck him. He congratulated Mr. Bowen on his success. He trusted that the era on which we have entered is only the beginning of a grander light, for the mind and soul of the people of Elgin and other cities.

Mr. Bowen told how in his travels he had frequently been asked, "Have you the electric light in Elgin?" and had had to answer in the negative, but say that the city was to have. Communication from other places had often gone to Aurora to see the light, but here for he should bring his friends. It wounded his pride to take them to Aurora. The mayor and council of a western city will visit Elgin next week to see our lights. Our railroad facilities are excellent, and as Col. Wilcox was acquainted with the history of our efforts at giving Elgin a second, this he knew the company would like to hear from him. Col. Wilcox said that we many congratulate ourselves on the progress that has been made. He was glad to see so fine a body of men—a better representative of progression than is often seen in our legislative halls. He looked back to the early days of Elgin, when the council was unasked and when each letter brought out the recipient $2 costs. Then he saw the advent of steam, and spoke of the bringing to this place of a line to connect with the Northwestern road. He predicted that that the day was not far away when ride-strictly would be used for warming our houses, and propelling our rail coaches with greater speed and safety than they are now run. We are yet in the infancy of the electric power. He spoke of the O'Hlerne Brothers, the young men full of vim, who went out of our city and received a training which fitted them to take a prominent part in so important a branch of industry as electric lighting.

Hons Mr. Crosby said his friend Bowen was had a suggestion which he desired him to offer. Mr. Bowen differs from the market men. They throw in lights when we buy hay, but Mr. Bowen was throwing in the living Direct because we took the lights.

The chairman in a happy manner referred to one of our solid and substantial citizens who has a sort of fancy—in other words, as all know, our friend R. F. Reeve, is a Grandmaster (Crosby, "Hadn't heard that before"). We should like to hear from him. Mr. R. was observed to the honor invested, upon him was very unexpected. He told of an old tenant who, when he departed from his house, left him a lot of candle molds. Patriotically the speaker commended to use them in lighting the city. He would feel pleased if the Russian previously mentioned should succeed in inventing even a one-wheeled watch to run by electricity. He would remember Olding before a railroad entered her when men were afraid if the road was built there would be no more use for horses; but it has often been demonstrated that as our facilities increase our wants increase. The lights of to-night are a great saving in expense compared with gas. All we want is first the light of knowledge shed upon the minds of men.

"I suppose," began Mr. Bowen, "we all feel proud of the fact that our merchants stand high in the community. We should be delighted to hear from done by one of the brightest of them all—Mr. for the Vanderpoels.

D. J. started in by saying that he was no speaker. He came to Elgin in 1856 to make the almighty dollar. Finding strong competition he had determined to coin money faster in another way. He would engage the top of the town, set Plymouth Rock hens thereon, and catch the eggs in a basket.

Mr. Bowen next called upon Prof. Schuyler, principal of the academy, who made perhaps the most eloquent speech of the evening. He told of arriving from Chicago in the evening, and as he was sitting in the house the flash of the new light flooded the academy and grounds so that it was almost as light as day. He went out of doors and read the letter he had begun, as easily as by daylight. This meeting of representative men was characteristic of all he had seen since he came to the United States. Our watchword is progress, and nowhere is it more clearly illustrated than in "our" country. Though he came among us late it was not too late. As Elgin is the best illuminated city in the United States, so is the United States the best illuminated country in the world, intellectually as well as otherwise. The great Goethe on his death bed cried out "more light." Had he lived fifty years later his cry would have been "More life" that he might see the wonders in the universe. The day is not far off when she light will be used for purposes of which we do not now dream. Fifty years hence the palaces of to-day will be hovels in comparison with the then habitations. I thank you, said Prof. Schuyler, for the privilege of being among the choicest of Elgin's citizens on this occasion (I take this in faith). Elgin is a good place to live in, and I will stay as long as you do.

The chairman mentioned the tower of Babel, which it took so long to build, and then referred to the structures which the O'Hlerne brothers rush up in a day. It would interest the company to hear from E. J. O'Hlerne. The latter said that he was much obliged for the honor conferred in the invitation, but he was no speaker and could hardly enter into an explanation as to tower building at that time.

Mr. Bowen then told the weight of the Fountain square tower and foundation, and said it could not pull out of. Ellwyer, Jr., photographer of City Clerk Sytiff, which he held in his hand. He said was made by the light of electricity by G. H. Sherman, whom all would be pleased to hear from. Mr. Sherman said that he had not expected to be called upon. The work done by him was simply a great end the brightest of them all—Mr. for the Vanderpoels.

In calling for Judge Lovell, the chairman pleasantly alluded to the "old system." Judge Lovell related a story about a sea captain giving one of his sailors a mixture of medicines No. 6 and 8 because he couldn't find No. 11, and he thought the combination would be the same thing. The speaker felt that a judicious admixture of gas and electricity would not be a bad thing.

D. H. Sherwood said he was glad we have the electric light. He spoke of the similarity between the illuminated heavens and the eternal, city, and said that were the streets paved one might imagine himself really in the eternal city.

Mr. Bowen spoke of the faithful, intelligent work done by Byron Clark in putting up the shafting at the gunsteps, and asked him to say a few words. Mr. Clark hoped he would be excused as he had never spoken in public.

In response to invitation Dr. Burlingame said that one good turn deserved another. Mr. Bowen had given us a splendid light and he wished to say that a young lady patient wanted to thank Mr. Bowen for it. The light that shone into her sick room was a great comfort to Her.

Ald. Wood proposed a vote of thanks to Mr. Bowen for his grand entertainment. This was done by a rising vote. Mr. Lord's remark that "The eyes have it" being greeted by loud laughter and applause.

Mr. Bowen asked Theo Grihl if he would explain what could be done with watches whose works had become magnetized by too close proximity to the dynamos. Mr. Grihl responded at some length, explaining the process of magnetizing and demagnetizing, and closed by saying he would be glad to see any present whose watches had been thus affected.

After the quartet and company had sung "America," which the host declared the grandest hymn ever composed, followed it with "Auld Lang Syne," and "Sweet Dy and By," all standing, the banquet was at an end; a most successful banquet-ing of our electric lighting has been participated in; the clock pointed to a few minutes past 1, and the electric light was soon shedding its beams for the guidance of homeward bound footsteps.

The Towers.

Singing the praises of the Vandepoels lights and of the concentrated success we must not forget the chief factor in getting the light before the people, the O'Hlerne towers, as substantial as it is handsome and admitted by all to be the best possible substructure to use in the best possible way of outside electric illuminating, viz., the tower system.

The towers are the invention of E. J. O'Hlerne, of the firm of O'Hlerne Bros. & Co. The Messrs. O'Hlerne have without doubt had more practical experience in the construction of electric light towers than any other firm in the country. During the past three years they have been employed in the building of these towers, several for the Elgin Tubular Tower Co., and wished that company ceased to exist, for its successor, the Detroit Tower Co. Since they have been engaged in the work, the Messrs. O'Hlerne have erected electric light towers of, various heights in the following cities:

CITIES.	NO. TOWERS.	FEET HIGH
Aurora, Ill.	3	150
Dundee, Ill.	1	150
Fargo, D. T.	1	50
Bowling Green, Ky.	1	150
Fairfield, Iowa.	1	150
Topeka, Kan.	1	150
Fond du Lac, Wis.	1	150
Dayton, Ohio.	1	220
Rock Island, Ill.	11	150, 180, 200
Macon, Ga.	3	160
Macon, Ga.	1	160
Macon, Ga.	1	160
Savannah, Ga.	3	160
Evansville, Ind.	3	150
Total.	32	

All of the above towers were built of tubular iron, or what is commonly known as gas pipe. Early in the year 1882 the attention of Mr. E. J. O'Hlerne was attracted to the impossibility of preserving the tubular iron after the tower had been completed, these being in no way of reaching the inner surface of the tubular iron. In places exposed to the extremes of temperature and moisture the rust from the rain beats on the inner surface of the iron will soon become so thick as to cause the bursting of the iron, corrosion will set in, and once begun will continue as long as there is unoxidized metal left in the tower. It therefore became imperatively necessary to use solid iron in the construction of towers, and Mr. O'Hlerne began looking about for something possessing the advantages of strength and economy of material. After investigating the merits of different forms of solid iron he found that could be used with safety the star angle iron, he decided to great interest at the old of Prof. Moses G. Farmer, of Providence, R. I., one of the most astute electrical engineers in the world, and to the combination of iron of Prof. Farmer resulted in the birth of satisfactory proof that star iron possessed the greatest amount of strength due to the least amount of material, excellence of class study and careful computation, on January 18, 1883, he filed his claim in the patent office at Washington, together with drawing of a star iron tower. The patent was granted June 12, 1883. In any structure the angle iron has been stated iron was adopted in preference to other forms. The government lighthouse board chose a tower for Bell Gale, N. Y. The superiority of material and purity of construction quickly demonstrated itself to investigators. It was recognized by Hon. George S. Bowen, president of the Anglo Electric Light Co., who had contracted to light our city by the tower system, and had first designed using the tubular iron towers. Mr. Bowen's views in the matter were commended in by a majority of the committee of the whole, the "Chicago" tract was ordered, all the aldermen being in favor of it save two, who opposed to the electric light and voted against the present pleading and no cause of objection to the tower. So the Elgin Tubular Towers were ordered, and the wisdom of the council we think very strongly demonstrated. Thus early the towers have had several severe wind storms to withstand, and in fact two or three of the towers were subjected to violent wind while in process of construction and were not affected in the least. Only an extraordinary violent storm could make the least possible inroad upon the handsome structures.

Seven of the towers were ordered by the Electric Light Co. six to be one hundred and twenty-five feet high and one, the Fountain Square structure, to be one hundred and fifty feet high.

A lengthy essay on the merits of the star iron is hardly necessary. Our people can see for themselves and all are pleased. The towers are a decided ornament to the city and give entire and complete satisfaction. They are in shape triangular skeleton frames of light material, each twelve feet wide, tapering from a wide and secure base to a point. The last tower to be erected, of two feet at the top, which is surmounted by a platform and railing in the center of this platform is an eight foot iron pole, which carries the top, from which arms are suspended the electric lights. The tower is fastened with steps twelve inches apart, and is provided with a platform at three steps, being directly above and below each other, so, and during the harmony of the tower. In truth they are models in every part of their structure, which is a thing of beauty and a joy forever. The foundations are provided with sockets for the reception of the ends of the four iron posts and girts, the sockets being drilled to receive the ends of the iron, and when the foundation is complete and setting through the star iron posts securely, the girts are then firmly in place. The sections are trussed with wrought iron rods which are also secured and riveted to the coupling, and extending from base to top of tower would without the aid of the steel bolts hold the complete firmly in upon the ends of the posts and girts. The sections are made with a round iron shouldered head upon one end and a thread on the other, the thread end which consists of two plates of iron with a hole in the center, each end being upon and resembling a rod clevice in which the bend of the rod is loosely confined, allowing it to be turned at any angle desired. The two plates being merely bolted together with a single bolt, allows them to form any of the different angles of construction of iron rods. The lower section of the Fountain Square tower is supported by a trussed arch which does away with the ordinary guy rods, as in the other sections. This arch is only used in places where trees are placed over side walks as on Spring street, so as to allow of pedestrians passing under the tower with perfect freedom. The tower, is covered with a heavy coating of mineral paint of a dull red color which should be renewed every

IRON.

THE WERDERMANN LIGHT FOR THEATRES.—A most successful experiment which lighted up the Opera House on March 30 is, at the Athenæum of the Rue des Martyrs, Paris, with the Werdermann incandescent light. The peculiarity of it is that it can be gradated at will for scenic effects, either by introducing resistance coils or varying the velocity of the dynamo machine. These experiments were witnessed by several influential members of the Municipal Council, who on the following morning proposed an inquiry into the propriety of adopting all the theatrical managers to light their halls with electricity.

THE ELECTRIC LIGHT AT THE CANNON STREET STATION.—The Brush and Siemens lights were set the other evening, which lighted up the City last week for the first time. The electric light was also used for the first time on the same evening at the Cannon Street Station. The arrangements consist of Gramme machines and Brockie arc lamps, and the work has been carried out by the British Electric Light Company who own these patents. Eight powerful lights of 6,000 candles each are suspended from the roof of the station at a height of about forty feet from the platforms; and there are eight outside the station. There are two circuits for the lights, five upon each, and the current for each circuit is produced by one of the large new type of Gramme machines introduced by the British Electric Light Company, which are a number of new lights in series. The same class of machine is used by them for lighting Victoria Station, Manchester, and numerous other places, and is being fitted for lighting the telegraph instrument galleries and letter sorting rooms at the General Post Office. Although so small a number of lights are employed at Cannon Street the station is filled by the electric light to an excellent degree. Although the British Electric Light Company have taken no part in the City lighting they have entered into a contract with the Liverpool Corporation for lighting about 5 miles of the principal streets of that city, and it is expected that the lighting of this large area with electric light will commence on the 1st May.

IRON.

ELECTRICITY AND GAS.—If the figures already available in connection with the electric lighting experiments at South Kensington Museum can be trusted, there is a very considerable margin in economy between gas and the electric light. About 700 hours during the year, and the expense of the electric light—the actual working expenses—is 1d. per hour; whereas gas formerly cost 10s. an hour. There is, however, 5d. per hour, to be added to this, to be deducted interest on capital and a sinking fund to cover the effects of wear and tear and depreciation.

THE ELECTRIC LIGHT AT GREENOCK QUAY.—The electric light has been used for lighting the Greenock Steamer Coal Quay with great success. Some time ago the Harbour Trustees, on the motion of Mr. K. M'Culloch, resolved to give the light a trial, and arrangements were soon thereafter made with the Clyde Navigation Trustees to have the light fixed on the Custom House Quay, so as to enable the Harbour Trustees to judge of the effect. Four temporary poles were put down in position, the lights from the batteries fixed thereon differing the light not only along the quay but into the two contiguous harbours, and for the first time in Greenock a large party was present at the inspection, which took place last week. The effect of the light was the theme of general admiration, and seen from the river the effect was brilliant in the extreme. The present arrangement is not on a permanent basis, but it is anticipated that a permanent arrangement will eventually be entered upon to have all the quays and harbours of Greenock permanently lighted with this system.

GAS v. ELECTRIC LIGHT AT THE DOCKS.—The Swan electric lamps, at present burning nightly in Mosley Street, Newcastle, were on Wednesday night last subjected to several thousands of the inhabitants, when the relative merits of gas and electricity as lighting agents were tested. The admission which the new lights had excited a general interest in the town, and a large crowd of persons assembled who in the course of the evening filled all the corner of the street over the shop where the lights are fixed. The effect produced by the lights was lighted on that occasion was really splendid, the whole street at the time—was really splendid, the whole street at the time—was really splendid, the whole street at the time—

THE BRUSH SYSTEM OF ELECTRIC LIGHTING.

(For Illustrations, see pages 308 and 309.)

No much more than a year has elapsed since the Brush system of electric lighting was first introduced into England, and we recorded at the time—December, 1879—the very satisfactory results of the first demonstration effected, which we then witnessed. Since that time the progress of the light has been as rapid as it has been favourable. We have occasionally had to notice various instances of its application, including the Great Eastern Railway, at Liverpool Street; the City and Western Railway, at Paddington; and the South-Eastern Railway, at Charing Cross: these applications culminating in its adoption for lighting a portion of the City, as reported by us at the commencement of the past month. The results there speak for themselves; and our own verdict was given in its favour at the time, and we believe we are correct in stating it to be the opinion of a great majority who have had the opportunity of judging of the brilliant and steady light which is the object upon the present occasion to refer to, and to do so as much as possible briefly, and more, or to point out its special merits—for this we have now before us to describe in detail the construction of the apparatus by means of which the excellent effects witnessed are produced. And this we are enabled to do through the courtesy of the directors of the Anglo-American Brush Light Corporation, who have kindly placed all particulars at our disposal.

From our previous brief notices of the Brush system it will have been seen that it is complete in itself, including as it does both the generator and the regulator. Moreover, the Brush Company manufacture their own carbons, so that the matter from first to last is in their own hands. This system is illustrated in the engravings at pages 308 and 309 of our present issue, and which represent the generator, the regulator, and their details. A perspective view of the Brush generator is shown in fig. 1. The most characteristic feature of the form and construction of the armature core, which consists of a ring, is shown in fig. 2, a cross section of which is generally rectangular, but in the direction of its diameter section it is alternately wide and narrow, as shown in fig. 2. It will be seen that the ring is formed up into as many sections as there are bobbins to be wound, by a number of grooves; in these the coils of insulated copper wire are wound, until the groove is filled up. Fig. 3 is a cross section of one side of the ring, and it will be observed that the intermediate thicker portion is also grooved out by a series of deep concentric grooves, the object of which is partly to reduce the mass and lessen the weight of the revolving armature, partly for the purpose of large industrial electro-magnets whose poles are expanded increasing the ring, and thus carrying away a portion of the air as it is presented to the magnetic poles as a means of reducing heat generated by the working of the machine, but chiefly side, leaving one pair of coils free from their direct influence by the reduction and isolation of local currents generated and this helps greatly in passing through the neutral region by induction in the iron, and which would tend not only to of the magnetic field. reduce the efficiency of the machine by diminishing the magnetic capacity of the armature, but also to produce a heating of the ring, and therefore of the coils, whereby a portion of the current would be lost through their resistance being increased. For a similar reason the interior of the ring is grooved out deeply so as almost to reach the coils; by this means all cross currents are effectually cut off, and Foucault currents are compelled in the direction which are not detrimental to the efficiency of the machine. This again, increases the area of radiating or cooling surface, and consequently helps to prevent the armature becoming overheated.

In the sixteen-light machine, which may be regarded as the normal size of the Brush generator, the armature ring is 20 inches in diameter, and it is wound with eight radial coils of cotton-covered copper wire of No. 14 B.W.G., whose terminal middle planes radiate from the axis of rotation, being distributed round the ring at equal angular distances apart of forty-five degrees. Each coil contains about 300 feet of wire, weighing about 20 lbs., and would therefore occupy grooves shown set coils about six abreast in or 1½ deep as in fig. 2. Fig. 4 represents the armature ring with all its coils wound. The two sides of each groove, and therefore within the machine being inconsiderable. of each coil or wire, are parallel to the central line or radial plane of the coil. All the coils are wound in the same direction.

The distribution of the coils around the ring, and the way in which the connections are made it seen at fig. 5. The inner end of each of the coils is connected by a wire to the inner end of the corresponding coil, at the opposite extremity of the same diameter of the ring, and the outer ends of all the coils are brought through the shaft of the machine, and are connected to corresponding portions of the commutator, where the currents are collected by copper plates or brushes, as we shall see later on. Thus the inner end of the coil is connected to A^4, which is the inner end of the coil 5; A^5 is connected to A^6, A^6 to A^7, and so on round the ring, and the outer ends B^1, B^2, B^3, &c., are all connected to the commutator by conducting wires insulated from one another. The two ends of each pair of diametrically opposed coils are, after passing through the shaft of the machine, attached respectively to two diametrically opposed segments of the same commutator, which segments are separated from one another and from any other pairs of coils. The commutator, which is attached to and rotates with the driving-shaft of the machine, is composed of a set of separate copper rings, of which there are as many as there are pairs of coils on the ring, the rings being cut through at two of their circuits of twenty segments insulated from one another on one side of the shaft by a small air-space about one-eighth of an inch wide, and on the other by a piece of copper separated from the segments by two smaller air-spaces. The arrangement is shown in fig. 6, in which A and B are the two segments connected respectively to corresponding coils on opposite sides of the armature, and stitched by an insulating material to the shaft S; C is the copper insulating piece, the object of which is to separate either of the flat copper bushes or collectors, which press upon the periphery of the commutator, from either of the segments during the interval occupied by one pair of coils passing the vertical, or in other words through the neutral position of the magnetic field. This occurs twice in each revolution of the armature, and therefore of the commutator. At the time when any pair of bobbins is in this way cut out of the general circuit, their own circuit is open, so that no current can circulate or be induced in them. By this ingenious arrangement each pair of coils has to remain in each revolution a period of rest equal to one-quarter of a revolution, or, in other words, each coil remains idle for one-eighth of its revolution, and the time the machine is running. So little is, in a great measure, due the very small development of heat in the Brush machine, and it proves to be another important element of efficiency, namely, that each pair of bobbins as it passes the neutral position of the armature coils and is therefore, incapable of doing work and contributing electromotive force to the general current, is itself cut out of the circuit, and thus two causes operating against the efficiency of the machine are eliminated.

One of the important features of the Brush machine is the arrangement of the magnets by which the magnetic field is produced, and by which the armature coils are, during their revolution almost continuously, passing through a very intense the magnetic field. Upon reference to fig. 1 it will be seen that the armature ring is closely embraced on each side by the most intense directions around the magnet, the inmagnets having their similar poles presented towards one another on opposite sides of the armature coils A A1, and M1, are held firmly together by the connecting bar, the two north poles N N1, while at the same time the corresponding bobbins A1 a receive the influence of the two south poles S S1, a current is therefore induced in the coils in the direction shown by the arrows, the current passing through the shaft S to the commutator C1, and so collected by the brushes B1 and B2, and so on round time the other portions of the circuit, which time the other portions of the commutator which time the other portions of the working armature bobbins are in contact with the brushes B1 and B2, by which the current is collected from the external circuit of the machine. The rectangular cross-sections of the sixteen-light machines as now constructed, as illustrated round the ring at equal angular distances apart of eleven coils, in which the four coils of the field coils, in the circuit, and thus two causes operating against the

Fig. 7 illustrates the connection between the armature bobbins and the magnet coils. M M and M' M' are the two magnets having their similar poles presented towards one another on opposite sides of the armature coils A A1, the field is produced by the two north poles N N1, while at the same line the corresponding bobbins A1 a receive the influence of the two south poles S S1, a current is therefore induced in the coils in the direction shown by the arrows, the current passing through the shaft S to the commutator C1, and so collected by the brushes B1 and B2, and so on round time the other portions of the circuit, which time the other portions of the commutator which time the other portions of the working armature bobbins are in contact with the brushes B1 and B2, by which the current is collected from the external circuit of the machine. The rectangular cross-sections of the sixteen-light machines as now constructed, as illustrated in the engravings, are wound with the four coils of the field coils, and therefore, incapable of doing work and contributing electromotive force to the general current, is itself cut out of the circuit, and thus two causes operating against the efficiency of the machine are eliminated.

Fig. 8 is a diagram, showing the course of the primary circuit, and illustrating the principle of the series system. The bobbins are in contact. It also shows the shunt-circuiting contrivances by which any accident to one lamp or irregularity of working cuts it out of the general circuit, without extending any disturbance of the activity in the series. In fig. 8 the two terminals of the lamp, which are placed in connection with the carbons, are shown at L and L1, and are connected through the two holders bobbins 11 and 10 in the shunt-circuit, which is shown thick and dark in the engraving, and connected with the carbons. The terminals of the carbons are in contact, the current flows through them, and by the vertical coils of the lamp to the terminal lamp, L1. The effect of this is to convert the solenoids, 11 and 10, into electro-magnets, which by its oblique action seizes the carbon plunger, N and S, lift one edge of the washer clutch, W, which by its oblique action seizes the carbon rod (much in the same way as a tent-rope tightener grasps its cord) and the carbon rod is released until its influence is balanced by that of the fine wire helix, which surrounds the thicker coil. The shunt-circuiting apparatus shown to the left of the carbons in the same figure consists of an electro magnet, T, wound with a thick and a fine wire coil similar to those of the regulating solenoids, but both wound in the same direction. When the fine wire coil of this magnet is complete, it forms a shunt of high resistance between the terminals, and therefore a short-circuit of low resistance. The fine wire is wound upon the current to the lamp, and when the fine wire coil of this magnet being in circuit with the fine wire of the regulating solenoids; it follows that, if, through a failure of the light, or through its becoming abnormally long, or through any considerable increase in its resistance, a larger proportion of current be diverted through the fine wire circuit, the attractive form of the electro-magnet, T, would be increased, and its armature, A, which is attached to the pivoted lever, B, would be attracted, and the contact pieces, K, be separated, and thereby be brought together, and the terminals would be short-circuited through the thick coil, and the resistance spring, R. By thus short-circuiting the terminals through a route altogether independent of either the fine or the thick wire solenoids, their magnetic action ceases, and either the upper carbon is dropped, or if it is burnt out, or from any other cause the arc is not established, the contact pieces, M and M1, are held firmly together by the attraction of the magnet, T, and the current flows past the faulty lamp to the others in the series, its extinction calling attention to it, while the other lamps become proportionately brighter.

We now come to the carbon pencils used in the Brush system, which, before being used, are a foot long, and are electro-plated with a thin covering of copper. They last for about twenty-four hours, during which time about 9½ inches of the positive and 4½ inches of the negative carbon are consumed. When the lamps are required to burn for a longer period double carbons are used, as shown at figs. 9, 10, and each is controlled in the same manner as the single carbon lamp, but the controlling apparatus is not duplicated. When the lamp is put into action the arc is formed between one of the pairs of carbons, and when they have burnt out the other pair automatically starts into action, and continues to burn until consumed.

The change from the one pair of carbons to the new pair is effected by very simple mechanical apparatus which will be understood by fig. 8 and 9. C is the hollow solenoid or sucking magnet, which exercises a magnetic influence upon the soft iron plunger, P. The raising or falling of this plunger raises or lowers the frame K by the intervention of the levers, L^1 and R^1, and the carbon rod, which pass vertically through the casing of the lamp, and V1 and W are the clutch-washers which grasp the carbons. One side of each of these washers passes between a pair of the four forming pairs of carbons, as well as the four intervening spaces its action is first to tilt the washers and then to grasp the carbon which the rod or plunger, P, carries. By the simple device of making one pair of jaws a little higher than the other pair, the one pair of carbons first begins to act, and continues to act after the corresponding carbon higher than its neighbour. The consequence is that only one arc is established, viz., across the lowest distance, and, in all the subsequent feeding and controlling, the pair of carbons first started are alone affected, because although both carbons are raised and lowered together, the lower end of the reserve carbon is always higher than the arc by the difference in the height of the two pairs of jaws on the frame K. As time wears, however, and, owing to the shortening of the consuming carbons, they can no longer meet when the frame is dropped, and the current by the same alley are again separated can only be transmitted by the reserve carbons coming into contact, and the circuit is thereby completed, the new carbons are separated, and the act between carbons to be controlled by the magnet and clutch in the same way as the first are wire.

Such is the Brush system of lighting, which, as we have said, is now in regular operation at several places in the metropolis, and is illustrated in the engravings at Charing Cross Station, the meeting-room of the Institution of the Westminster Tower and Westminster Palace Yard, and at large area of the City—and also the machine-room of the company's works in Lambeth. The Treasury has also substituted the General Post Office to make a preliminary contract with the Anglo-American Electric Light Company for a machine and sixteen-lamps, which will be employed in lighting the letter-sorting department. A electric light apparatus and lamps is now being put down at the Rhymney Ironworks. As showing the progress of the Brush system in America, where it is in great favour, we may mention that, during the twelve months ending December last, the American proprietors sold no less than 275 machines and 3300 lamps, of which type of the latter were for use in the United States. This is no wise belies the experience of the Brush system in our own country. With regard to the recent temporary failure of this system in the City experiment, it is to be observed that the cause was not attributable to any defect in the system, but to the insulation of the conductor, which was not apparent until the recent heavy rains descended. This has been remedied, and can be guarded against in future.

THE MANCHESTER ELECTRICAL EXHIBITION.

THE Manchester exhibition is making slow progress towards completion, but many of the exhibits have not yet got into working order, and there are here and there spaces which have as yet only been partially occupied. In the engineering section a moderately good display is made of different types of engines for various purposes, but chiefly designed specially for electric driving. Messrs. Boskin & Parkes, Salford, exhibit the "Sanden," one of the newest types of horizontal engines specially available for electric driving. It is fitted with high pressure expansion gear, with automatic sensitive high speed governor, or with simple automatic expansion gear. The engine shown is an improvement upon the one exhibited at the Crystal Palace, the outer bearing being carried on an arm cast on the engine base, and the fly-wheel being long enough to be carried through the arm. By this means the engine is made self-contained, and the upwards pedestal in previous engines, which increased the labour of setting, has been dispensed with. The same firm also exhibit an excellent vertical engine, specially combined, designed to meet the requirements for electric lighting in a limited space. Messrs. S. S. Stott & Co., Manchester, exhibit their combined engines and fire pumps for cotton mills and works, which in repeated trials have given very good results. Andrew Handyside & Co., Derby, have an assortment of their portable forges with patent blowers. Mr. S. Berland, of Manchester, late works manager to Messrs. Sharp, Stewart, & Co., exhibits a new injector, his own patent, for which it is claimed that whilst the lasklessness of those at present in the market is avoided, the proportions of the nozzles ensure a prompt and continuous action, unaffected by the several lifting and working pressures. At the same time there is provision for ample range in the pressure of steam employed. The Manchester pumping engine, which is shown in action, and attracts a good deal of attention, is exhibited by C. Fearn & Co., Manchester. Excellent metallic pistons and packings, which are extensively used both in stationary and marine engines, are shown by William Buckley & Co., o Sheffield; and Cowburn's patent dead-weight safety-valve, of which large numbers are also in use, is exhibited by the Cowburn Safety-Valve Company, Manchester. Elliott and Eastwood, Manchester, show their fuel economiser with spiral scrapers, which is operated by a "Worthenroth" gas engine. John Chadwick & Son, of Salford (whose stand is not yet completed), are putting up several fine specimens of their engines, including one of the horizontal type, 30 horse-power, with 4-inch cylinder 20-inch bore; a double-cylinder diagonal steam-engine, with 7-inch cylinders and 12-inch stroke; and a vertical engine, with inverted cylinders of 6-inch bore, and 8 horse-power nominal. Benjamin Goodfellow, Derby, exhibits Matthews' patent combined high-speed triplex engine for driving direct dynamos, pumps, fans, and other high-speed machinery. An improved flocking machine (Jones's patent), consisting of centrifugal brush wheels, fixed in a compact case, with fan and treadle, and so arranged that the emery-cloth can be readily changed as required, is shown by Thomas Matthews, Manchester; J. Proctor, Burnley, has an excellent exhibit in his new patent mechanical stoker, which consists of a barrow wheel, spring, and shovel, the wheel having a much easier motion than the type used in a forward movement, whilst a further improvement is introduced by an arrangement of the men and near bar, which enables differences with the rollers for crushing and with the dividers to be run less, which enables the machine to feed not only small, but large and other larger qualities of stone and coal. Crosby Lowe and Co., Manchester, have a large stand. J. Heall & Co., Cardiff; and Williams & Morgan, engineers and blower for steam boilers, and Hall's patent water heater, by Williams & Son, Cardiff. J. Lawson, Gateshead, has a three horse-power engine driving Siemens dynamo, and Robey & Co., Lincoln, a four horse-power vertical engine which will also be employed for electrical driving. Of gas engines there is an excellent display, but these are specially dealt with in another column. In the electrical section a number of the exhibitors have not yet got their exhibits installations forward yet in working order, and this department as regards electric lighting is therefore incomplete. The principal exhibitors are the Edison-Electric Light Co., who exhibit a number of their incandescent lamps, the driving power for which is obtained from an eight horse-power "Otto" gas engine; the Electrical Power Storage Co. (Limited), London, who have not yet completed the arrangement of their stand; and Messrs. Pilsy, Sanderson & Pike, who make an interesting display of electric appliances, for the most varied purposes. Amongst these are electric gas signals, for use between the engine-house on the pit bank and the shaft bottom, and for underground signalling. A specially new feature in these signals, which is accomplished by a new application of relays, is that the bells are rung at both ends when the wires are in use. For signalling underground the arrangement is most simple, not by merely pressing together two bare wires at any part of a pit road a bell is rung simultaneously at both ends—at the pit eye and at the workings. In the case of runaway serves on a tramway, or of any other accident between the workings and the bottom of the shaft, the signal could by this means be at once given from any point. The same firm also show a magneto shot fuse, for use in mines or pit sinkings. The apparatus consists of three magnets of considerable size, enclosed in a box, and by a simple arrangement magnetism is drawn from the magnets, and being transferred to a wire, a magnetic spark is conveyed to the shot to be fired. The instrument enables the operator to fire a shot at any distance which would be required to ensure the safety in conducting the operations. A portable electric bell, consisting of a battery and bell enclosed in a case with 20 feet of covered wire and operating button attached, which can be instantly set up at any place as desired, and the Climax motors, for the small machines, such as light lathes, sewing-machine, &c., are also exhibited by the same firm. Altogether, the apparatus there is a fair collection of various types of furnaces, heating and cooking stoves, showing some of the latest improvements in this direction; and the exhibition, when complete, will be one of a generally interesting character.

Iron, Feb. 9th 1882.

THE VIENNA ELECTRICAL EXHIBITION.—We are requested by the council of the Society of Telegraph Engineers and of Electricians, to state with reference to the International Electrical Exhibition, which will be held in Vienna, in August, September, and October next, full particulars of which appeared in our number for March 10th, 1882, that at the request of the Austrian Minister of Commerce, and of the managing committee of the exhibition, the council of the society have appointed a committee for the purpose of receiving applications from the leading British exhibitors, and for promoting generally the formation of a British Section. All communications should be made as early as possible, and should be addressed to the secretary of the Society of Telegraph Engineers and of Electricians, 4, The Sanctuary, Westminster, S.W.

Iron, Feb. 23. 1882.

ELECTRICAL NOTES FROM SCANDINAVIA.—The electric light is becoming very popular in Sweden. In Stockholm arrangements are now being made for lighting parts of the city by means of the Siemens-Hefner-Alteneck light. The Swedish patent of the electric machine invented by a Swedish engineer, Herr Wenström, has been purchased by the Elektriska Aktiebolag, of Stockholm, for £1,400. The Swedish government have under consideration a proposal for settling the disputes with the telephone companies. Probably most of the telephones already laid down will be purchased by the government. The Bell telephone is coming very great use in the towns of Norway. Nearly all the larger cities possess now the necessary apparatus, and in Christiania alone about nine miles of wire have been laid down, and the number of messages amounts to 8,000 per day.

JOEL'S INCANDESCENT ELECTRIC LIGHT.

JOEL'S INCANDESCENT ELECTRIC LIGHT.

WE recently noticed the successful application lighting to the establishment of Messrs. George Angus and Co., of Newcastle-on-Tyne, and we now proceed to explain the system in detail by the aid of the annexed illustrations, of which fig. 1 represents one form of a complete lamp, fig. 2 the same representing the details. The light is produced by the heating to incandescence of the end of a thin carbon rod or pencil, which forms one electrode, and which is continuously fed through special and simple contact jaws against a fixed cylinder of copper forming the other electrode. The length of carbon between the jaws and the copper cylinder is about 2 inch, and from this the light emanates, chiefly, however, at that part near the fixed cylinder, where it becomes pointed by the action of the current, and therefore more intensely heated. In addition to the light produced by the incandescence of the carbon, there is also the glow or flame from the sides of the burning carbon in the copper cylinder similar to the flame of an arc light—the light thus taking an intermediate position between the purely incandescent system of Edison and the arc lamp of Swan. A peculiar feature of this light is, that the incandescent point of carbon becomes slightly coated in sharp, crystal like a manner, where it wastes away, and is replaced by the gradual forward motion of the pencil, so that the electrode remains intact, and lasts for any required time. The carbon rods are from 2 to 4 inches in length for lights of 100 candle-power and upwards. The carbon rods are of $\frac{1}{4}$ inch diameter and $\frac{1}{8}$ inch in diameter. In a table of the results of different methods of measuring the lighting given by Professor Adams, at the last of his lectures on Electric Lighting, delivered at the Society of Arts, it was shown that 215 candle-power per horse-power is obtained with this system.

The improvements in the lamp consist chiefly in the simplification of the mechanism in connection with the contact jaws, between which the lateral pressure of the jaws and the feeding of the carbon pencil are attained by the combination of one weight as shown in the diagram, fig. 2; the lateral pressure being thus always proportioned to the downward pressure. Also in the details for making the lamps in the same circuit dependent of each other, and its general adaptability for the purposes of domestic and interior lighting. Referring to the sectional view of the lamp, fig. 2, E is the fixed copper electrode with the point of the carbon pencil, c, pressing upon it. The contact jaws are shown at J. The weight, W, which actuates the jaws, is suspended by the continuous cords to the top of the lamp, B, the cords then passing down through the weight and under one of the rollers, R, up again through a roller attached to the carbon pencil-holder, then back through another roller at R, and ending at the weight. The rollers, R, are attached to a light tube, F, which passes down through a nipple, N, and terminates in a flange under the horizontal arms of the cranked jaws, thus producing the lateral pressure on the carbon. The top of this tube has also attached to it the armature, A, of an electro-magnet, S, wound with fine wire, and so arranged that if on are should form between the carbon, c, and copper electrode, E, the electro-magnet, S, would come into action and free the jaws, J, from lateral pressure. The carbon-holder is also arranged (fig. 3) so that when the carbon pencil is partially consumed the lamp is short circuited by the lever at 1, making contact with the arm carrying the copper electrode.

The stem of the lamp, C, c, is formed of metal tubing, cut in halves and hinged, each half forming part of the electrical circuit. When the lamp is opened for the purpose of inserting a fresh carbon, the lamp is automatically short circuited in the act of opening by the button, T, fig. 2, so that it is rendered perfectly safe in handling by the most inexperienced. In the form of a complete lamp, shown at fig. 1, it is fitted with chandelier suspension similar to gas-lamps, and can be fitted by ordinary gasfitters. This suspension allows for raising and lowering the lamp, for putting in fresh carbons, and attending to the lamp generally. We have personally inspected the system in operation, in the offices of the Electric Light Agency, 32, Queen Victoria Street, London, and can testify to the satisfactory results given by it. The current is generated by a Gramme continuous current machine, which is driven by an Otto gas-engine. The arrangement for lighting the offices, the experimental shops, and engine-room, a light being also placed outside the building. The lamps are arranged one in each office, the illumination being very brilliant. In the experimental shop, two lamps have been substituted for fifteen gas-burners, with greatly-increased results as regards light, the light is of a warmer appearance than that produced by the gas system, and is perfectly steady and very pleasing in effect. The lamps can be turned on or off at the side of the room or at the lamps themselves, and are made in a strong and practical way, fit for ordinary wear and usage. In fact, the lamp appears to be one which exactly meets the requirements of ordinary indoor illumination.

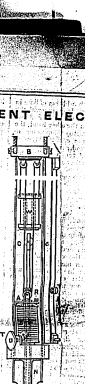

FIG. 3.

FIG. 4.

great throughout the whole of this range as it is at the final-named temperature, it is still, in his opinion, extremely unsafe to put any work whatever upon mild steel within these limits. These facts cannot be too widely known, as the knowledge may lead to the prevention of some of those apparently mysterious failures which have occurred in the working of steel. We need hardly remind our readers that some important information on this subject was communicated by Mr. Daniel Adamson, at the meeting of the Iron and Steel Association at Paris in 1878. He there showed that at certain temperatures steel lost its ductility and became brittle.

ELECTRIC LIGHTING IN THE CITY.

OUR readers are doubtless aware that a portion of the City is to be illuminated experimentally by the aid of electricity. Three districts, in fact, are to be electrically lighted, one by the Brush, a second by the Siemens, and a third by the Lontin light. The Jablochkoff light was to have illuminated one district, but circumstances have arisen which prevent this arrangement being carried out, and this district has been allotted to the Lontin light. The district which has been undertaken by the Anglo-American Brush Electric Light Corporation embraces Blackfriars Bridge, New Bridge Street, Ludgate Circus, Ludgate Hill, Saint Paul's Churchyard (north side), and Cheapside, as far as King Street, and is the second largest of the three districts experimented upon by the City authorities. The lights are thirty-two in number, although forty lights could be maintained on the same circuit. The whole of this section is worked by a single small copper wire strand of 8 B.W.G., and 8,000 feet, or over 3 miles, in length, starting from the works of the Anglo-American Company, near Waterloo Station. The whole number of lights are connected in one circuit and worked by one machine; theseeing for the entire circuit about 3 horse-power indicated. The machine is worked by the same engine which works the lights forming at Charing Cross and Waterloo Stations, and also all the machinery and the testing circuits of the company's factory. The lamps are fixed upon the present gasstandards, standards above which they are raised about 2 feet 6 inches. The street lighting is in fact, is being carried out by the Brush Company, so as to illustrate the utilisation of existing lamp-posts, with the view of demonstrating how easily and cheaply a change from gas to the electric system of lighting streets can be effected. If it is considered that this general effect would be increased by using higher standards, they can, of course, be easily fixed; but in the experimental trial, such as to lamps and lamp-posts, the greatest economy has been aimed at. Keeping this point in view, all the lamps in the district lighted by the Brush Company are of a power which is estimated to be best adapted for such a purpose, but light of any greater degree of power can be substituted, if required.

The district allotted to Messrs. Siemens Brothers and Co. extends from the south side of London Bridge, through King William Street, the Poultry, up to the Guildhall Yard, taking in Queen Street as far as Queen Victoria Street. The number of lights employed is thirty-four, comprising six powerful lights, and twenty-eight smaller ones of about 200-candle power each. The six large lights are mounted on latticed iron poles about 80 feet above the level of the street, and are disposed, one in Adelaide Place, a second at the King William Statue, a third at the junction of Lombard Street and King William Street, the fourth in front of the Royal Exchange, the fifth by the Mansion House, in Queen Victoria Street, and the sixth in the Guildhall Yard. This last light is nearly three-quarters of a mile from the dynamo-electric machine, which generates the current for it. The twenty-eight smaller lights are fixed on iron posts resembling ordinary gas lamp-posts, about 20 feet from the ground, and interspersed between the larger lights in the best manner to secure a good general illumination. Each large light is supplied by its own dynamo-electric machine, separate conductors being led from the dynamo machines to each lamp. The twenty-eight smaller lights are arranged in four groups of seven lights each, and are fed from two separate current machines, each supplying two groups of fourteen lights. It has been thought advisable to make this subdivision for convenience in working, instead of arranging all the lights in a single circuit, as could easily have been done.

The regulators, or lamps, are constructed to take carbons of sufficient length to last eighteen hours without renewal. They are enclosed in lanterns fitted with reflectors designed to intercept and throw down the upward and horizontal rays. The lanterns are suspended from the tops of the latticed iron poles by projecting brackets, against which they are drawn slightly to prevent their being blown about by the wind. A door is let down into the street a platform is lofted to the pole, upon which the lantern is lowered when it becomes necessary to replenish the carbons. The guide wires, passing through openings in the reflector, being stretched between the platform and the bracket to guide the lantern during its ascent and descent. The leading wires which convey the current from the dynamo machines to the lamps consist of strands of copper wire coated with gutta-percha. With the exception of London Bridge these conductors are laid for protection in cast-iron pipes, which run continuously to the farthest lamp. Those crossing London Bridge are provided with an outer sheathing of iron wires and rest upon the broad ledge of the parapet. At the foot of each post is placed a cast iron box, in which the conducting wires from the lamp join those which come from the machine. The electrical generators, and their steam-motors are situated in the basement of a warehouse in Old Swan Lane. With a view to provide against possible accidents, the generators are divided into two equal groups, each of which is driven by a to-horse power nominal steam-engine by Messrs. Marshall, Sons and Co., of Gainsborough. A third steam-engine of the same power is placed, as a reserve, between the other two, and so arranged as to be able to drive either set of generators, when their own engine requires cleaning. In the room over the engines are placed the instruments for measuring the current and for switching it from either dynamo machine to either lamp, and other accessories. Here also indicators are provided so that the electrician in charge can see at a glance if the machinery is working regularly.

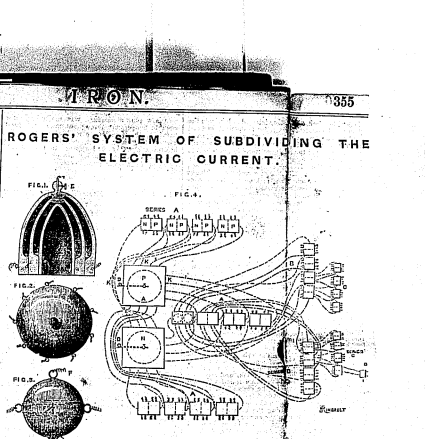
Such are the details of two out of the three systems of electric lighting which by their inauguration last evening mark the commencement of the largest and most important experiment in Electric Lighting that has yet been carried out in London. It is to last for a year, and the streets are to be illuminated by the aid of electricity all night, thus entirely superseding the gas. The district allotted to the Lontin system comprises Southwark Bridge, Queen Victoria Street, Queen Street Place, and part of Queen Street. This light has taken the place of the Jablochkoff, and was to be in operation by the 31st inst. The length of streets covered by the various systems, and the cost of lighting, are as follows:—The Brush system, 1,618 yards, at a cost of £1410; the Siemens system, 1541 yards, at a cost of £1200; the Lontin, 1703 yards, the cost being £2250, the same as was to have been paid for the Jablochkoff light. The total cost of the experiment will thus be £4860—but the expense of gas lighting for the year will be saved. It will be observed that there is a considerable difference in the cost of the three systems, according to the figures furnished, the lighting by the Siemens system will not exceed in cost that of the old lighting by gas, the sum to be paid to the Brush Company being fixed upon that basis, viz., £960, an amount which, we presume, will leave them a very substantial working profit if the lighting is carried out upon an extensive scale. The total to be paid as above for the Lontin light, inclusive of installation, is £1150, as compared with a total of £2250, to be paid for the trial of the Lontin system, and £2250 for the trial of the Siemens system, over an approximately equal area. It will be interesting to see, therefore, whether the lighting by the Brush Company, upon the commercial principle of competing with gas in price, and at the same time affording an increased volume of light (the only practically useful result to be attained by electric experimental), will commend itself to the public sufficiently to ensure its general adoption. With regard to the appearance of the illumination itself we can only say that it forms a splendid electrical display, the pains being unquestionably carried off by the Brush light. We cannot, however, say that we regard the standards with feelings of unmixed satisfaction, but when we get the best light fully developed in practice it will perhaps be time enough to criticise the accessories.

ROGERS' SYSTEM OF SUBDIVIDING THE ELECTRIC CURRENT.

ABOUT a month since we placed before our readers a general outline of the ingenious system of subdividing the electric current devised by Lauchlan Rogers, of Bartholomew Close, London. At that time, the patent not having been completed secured, we could not enter into detailed particulars, but we promised them at an early date a full description, a fulfilment of this promise we now place before them. We may premise that Mr. Rogers has carefully watched the various propositions for subdividing the electric current, but being convinced that the complete subjugation and control of electricity had not been accomplished, he brought forward his system, which, we understand, he had completed and worked under eighteen months ago. The apparatus consists simply of a receiver for each pole of a battery or magneto machine. These are contained, for convenience sake in the first instance, in two separate boxes; from these boxes, that is from the receivers contained therein, proceed twelve wires—that is, twelve from the P, or positive pole, and twelve from the N, or negative one. These twelve pairs of wires are divided into twelve different boxes; these boxes contain a positive and a negative governor, and from each of them proceed four wires, so that at this stage in series A there are forty-eight circuits. Each one of these circuits is carried to four more boxes, being series B; again, from each pair of wires four of which there are four from each box, wires are carried to series C, so that at each box in series C has four complete circuits the result is a grand division, subdivided into sub-sub-divisions; are the original current which entered the receivers, P and N, in two wires from the battery or machine has been finally subdivided into 768 circuits or lights, as the case may be. Fig. 1 is a section of one of the receivers it is not, however, necessary to have the two interior cases for the governors or for the distributors, which may be of the form shown in fig. 3—a simple copper globe of small dimensions. The small rings at the top and bottom can be used as convenient, either one or the other, for connection with the previous divider; the rings on the periphery are for the purpose of receiving the wires to go out on duty. Fig. 2 is a plan of fig. 1, and illustrates the method of drawing off from the mains either P or N. Fig. 4 illustrates the method of the division and subsequent subdivision.

It will thus be seen that the statements made in our previous notice as to the simplicity of this invention are fully borne out, and that this invention is one of a very common-sense character. It will also have witnessed the subdivision of the electric current as produced by one or more machines into a series of twenty-seven vacuum tubes, three on each of nine circuits, and has also seen the light thereby greatly increased by Mr. Rogers. The circuits, moreover, were detached one by one without in any way interfering with the remainder. We have seen to be enabled to carry the subdivision of the system to a dynamo-machine, which will practically test the value of the system for subdivision of a subdivided light.

Before concluding, we may refer to the various inventions which Mr. Rogers has given to the world from time to time, some of which were described and illustrated in our old series—the *Mechanics' Magazines*—for back at that time his life-saving apparatus is perhaps one of his best known and most useful inventions, and it is one which we illustrated and described at page 196, vol. VI. of *Iron*. Amongst his other inventions are his automatic temperators, his system of night signalling at sea, his alarm gun, his clip for mooring and unmooring boats and ships, his cork-cutting machine, and lastly his water motor for working electric lighting machinery, which we described and illustrated in our issue of the 6th inst. Such are some of the results of Mr. Rogers' fertile mind; they indicate that he possesses a wide range of inventive power, and we trust in the present instance his creative faculty will be rewarded with the success it deserves.



ROGERS' ELECTRIC LIGHT.

THE operation of the subdivision of the electric current is the most important and difficult of the whole series in connection with electric lighting. It has been solved in various ways by various inventors, but only to a limited extent, that is—as far as we are aware—none of them, down to the present time, has quite succeeded in dividing and subdividing the electric current from its original source more than by the aid of the one pair of poles forming a circuit. What has not been effected in subdivision may be represented by a tree with its trunk or stem, from which shoot the main limbs, which again bear branches which in their turn carry the twigs. Now a system of electrical subdivision which would present an analogy to this would at the same time present a perfect solution to the problem at issue—other things being equal. Such a system of subdivision we have just seen, and from the demonstration we witnessed we have no option but to say that so far as that demonstration went it proved the electric current to be perfectly, absolutely, and to the most extreme limit, subdivided. The system which affords these results, which we have certainly never seen attained before, is that of Mr. J. Harding Rogers, of St. Clement's House, Lombard Street, London, whose name will be familiar to most of our readers in connection with the rocket life-saving apparatus bearing his name. We have been permitted to examine the details of the system, but the patents are not yet being quite completed, we are not at liberty to explain them, although we shall very shortly be in a position so to do. We may say thus much, however, and that is that the system is of the most simple and practical nature, and bears the impress of the mechanical instincts of the mind by which it was developed. It did not, however, spring suddenly into existence in its present form, the original conception having taken a long time to perfect, and only step by step has it been developed. As it now stands, however, and as presented to us, it certainly marks an important epoch in the history of electrical science.

Although we may not describe the details, we may, however, indicate generally the arrangements. In order to explain what we saw done by Mr. Rogers. The apparatus, so far as external appearance, consisted merely of a bi-chromate battery and 1-inch coil. From the poles of the coil the two conductors, positive and negative, were led each to a commutating box containing the dividing apparatus which is capable of effecting eighteen divisions of the main current, although only one wire was used in the experiment, that being sufficient to illustrate the principle. From each of the accumulating boxes a single wire proceeded to a dividing box. From this box, again, eight pairs of wires could have been led to eight other boxes for the further subdivision of the current, but five pairs were considered sufficient. These five pairs of wires were led, one pair to each of five boxes, where the current was further subdivided, and from these boxes wires forming nine circuits were led. Twenty-eight circuits could have been formed had the battery power been sufficient. On these nine circuits were placed twenty-seven lights represented by vacuum tubes, three on each circuit. The battery having been started the twenty-seven lights made their appearance simultaneously and distinctly, and as remained to the end of the experiment. Circuit after circuit was detached without in any way interfering with the others, and so far as the experiment went it satisfactorily demonstrated the practicability of dividing, re-dividing, and again subdividing the electric current so as to render it available for the smallest apartment, whilst at the same time it is under perfect control. Each apparatus, moreover, is in itself an accumulator, or governor, and a sub-divider. This perfect subdivision was demonstrated to the sense of touch by means of a medical battery, and to that of hearing by means of a series of twelve electrical bells, as clearly as it was demonstrated to sight by the vacuum tubes in the circuit.

This, however, is not all that Mr. Rogers has done towards advancing practical electricity. He has devised an exceeding simple motor for driving the current-generating machines. He uses water, and by the aid of a turbine of novel construction, having a perfect governor at its head, he obtains a perfectly steady motion, and by simply utilising natural laws he obtains a power in the most simple manner. The result is, that we have the two main requirements of electric lighting—a steady driving power and the subdivision of the light—perfectly met, as shown by the experiments. The practical test has yet to be made, but it is difficult to see how it can plausibly prove less successful than the experimental trial. Until it does, we shall hold that Mr. Rogers has successfully met the two most important requirements of electric lighting as regards its commercial success.

April 7, 1882.

IRON.

THE CITY AND THE ELECTRIC LIGHT.—At the meeting of the City Commissioners of Sewers on April 4 a letter was read from Messrs. Siemens, the electrical engineers, commenting on a statement publicly made by the Chairman of the Commission that their system of electric lighting in the City was nearly four times as dear as the cost of gas. They pointed out (in effect) that much of the cost of the lighting had been entailed by the merely experimental and temporary nature of their early installation, as the provision of expensive machinery that it would have been unnecessary to expect if the contract had been more permanent, and if they were permitted to supply private houses in the same district with the electric light. They also urged that the comparison as to the expense of gas and electric lighting to the disadvantage of the latter were always made under the supposition that the lights were of equal brilliancy, whereas the electric lights were far more powerful than gas. Mr. Fellow, the chairman, stated that in the district lit by the British system the contract price was £566, as against £500 paid for gas; in the district worked by the Limtin system the price was £1,460, against £970 for gas; and in the Siemens district £1,170, as against £612. The new contract submitted by Messrs. Siemens, so far from being cheaper because the experiment continued, was £1,500, instead of £1,170, being nearly six times dearer than gas. On the motion of Mr. Jones it was referred generally to the Streets Committee to consider how far the companies might be permitted to light private houses and shops with the electric light within their respective districts.

LIGHTING TRAINS BY ELECTRICITY.—A trial has been made of a system of lighting a train by electricity by means of Faure's battery, on the Prussian State Railway near Frankfurt. The system is stated to be different from that employed by the London and Brighton Company, the apparatus being set in motion by a transmission of power from the wheels of the trains. The current of power not required for the electric lamps whilst the train was in motion was used to fill Faure's batteries, so that when the train stopped these batteries could be used to keep the lamps burning.

Iron, Sept. 15, 1882.

EXTENSION OF ELECTRIC LIGHTING.—The Gare de l'Ouest, at Paris, has been illuminated with the Edison incandescent light. The same system has also been introduced into Besançon, the motive power being furnished by a waterfall about a mile distant. We see it stated that proposals have been submitted to the Markets Committee by the Metropolitan (Irish) Electric Light and Power Company for lighting the Central Meat and Poultry Markets with electricity.

property could be effected annually, more than twice; hence positive notice to the approach of the most dangerous storm-direction, pulsie, and this only at certain with the means of obtaining such prior warning; the seaman is he chooses, by up until the danger is generally so make for transmitting the sands of vessels' grounding our channels Now, if by means of the stations pre-either, thirty-six hours' positive notice a service of steamships vessels could ed the coast, such running a couple of more through the most dangerous parts and giving warning to all vessels in their of be prudent to run further. Such only be valuable on account of the cer- formation conveyed, but in the present ones than useless.

many every service rendered by these s in the way of postal, telegraph, intelli- other matters relating to the shipping to e needless to state, be of the utmost value shipowners would be enabled to forward he officers of their vessels, direct their receive notice of their progress and con- ts of four days or so. Disabled vessels ligence of its position, and await provided crews would be within two days' ard, should it be ascertained that these ers, not of any value or importance, but ould not there was every great expense be earned in the prosecution of the opened in this paper, and the author is ion that has been made of the exigencies emand the practical carrying out of such r reasons, then, the desirability of such ave in a position to briefly consider what ntial, and what conditions they should meet

place, the absolute safety of the staff ay should be provided for. The structure, floating body, should be capable of with- lutest accidental shock, such as might be by collision with a ship or iceberg, without ial damage; not only on account of the value of the expensive structure, on the one as in case of its establishment, its presence d upon the other. For there is no more vicious that its floating power should be per- hold depend entirely upon some practically solution. Secondly, although placed in a ed position, the mariner should be so worked as to allow sufficient deviation to be purpose of clearing such irresistible force as ght about by the passage of an iceberg, or of the mariner's intervention. Thirdly, ervation; it should, of course, be capable of a favourable position. Finally, the vessel ld be in every way seaworthy, and of suffi- ly strong construction to withstand hurricane or ch it cannot sufficiently discharge its functions ly, and a signal, telegraph, and meteoro- ys.

ppose to encompass these points is to provide ritual structure, so constructed, floated, and it it will float in an upright position with great, so upper part is to be practically a light-house steel plates and framing for the sake of the tension of strength with a minimum of weight, much dimensions as to provide accommoda- ring machinery, steam power, electric light n of all instruments, stores, and tackle required ant working of an institution, as also comfortable accommodation for a somewhat of officers, assistants, and keepers. The on of the structure would be occupied by a ral of most less specific gravity than water ference cork-wood and pitch), which would ss and unsinkable floating power. This floor would be packed into radial cells or compart- ided by a steel plate and frame partition, floor or deck to the lighthouse, and in- the floating material. By this arrangement cork were to waste or rot, a single cell at the remainder, and the vessel would not be ed. Access to the interior would be obtained ance to the centre of the floating material, tube to the several compartments, or, sec- ently to admit of periodical inspection. This ld be in the centre of the cast lantern, which immediately below. The lower portion of the ld be intended to act as ballast to the upper addition to the weight of the latter to counter- ed by the steel and framing, would be con- heavy framing and plates for that purpose, and ballast would be admitted. The weight of iron, or suit- ld be added to the lighthouse proper.

ion of the structure would be constructed and protected with concrete or ed for the purpose of resisting the surface disso- ly encountered, but which might become attacked, ion of the lighthouse proper, and the cast-iron ight be made for the purpose of resisting and similar arrange- ight be made for the purpose of resisting and

The floating body would be maintained in position by means of chains leading to a sufficient height above the water-line, and moored to sinkers, of the structure would be sufficiently independent of any hollow; so water, or other liquid, would be admitted to the cells of the floating body, so that the buoyancy of the floating power would be unaffected by the admission of water into the cells of the lighthouse proper. The arrangement comparatively simple, and the author is of opinion that it would be found to answer well. The rising and falling motion of the floating body, and consequently of the lighthouse proper, would be counteracted by passing waves would be counteracted by the action of the arrangement and one which would give very ample accommodation and floating power, so as to speak, in erecting the lighthouse lower on, and attaching the counterweights a much greater set of dimensions, in which the whole of the apparatus and stores, and a few suites of apartments and the floating material could be amply provided for. The lighthouse tower might also be of a somewhat lighter construction than in the previously described arrangement, and consequently a correspondingly lighter structure would be required. A feature possessed by the latter in this case would be, that it could be put together in sections, which might afford more facilities in erecting. The lower deck would be convex in form, and shutes or ports might be arranged for relieving the deck of any sea which might be shipped, and similar provision would be made with the upper or lower deck. All hatches would be made specially strong as any other part of the deck, and strongly arranged at intervals round the base of the light-tower, in order to afford a means of egress always on the leeward side. As in the previously described arrangement, a sufficient margin of safety would also in this case be provided by carrying up the inhabitable packing, to a sufficient height above water-line. But the author is decidedly of opinion that the advantages of this latter arrangement would be more than counterbalanced by its liability to be greatly affected by the action of the sea, which might cause it to ride heavily.

The mooring machinery would consist of large rope drums made to revolve by worm gearing driven by bevel wheels capable of being simply thrown in and out of gear, and mounted on the same shaft, actuated by a steam-engine. The end of each mooring rope is made fast to a separate barrel, and by having suitable gear for each attachment, uniformity of strain on the rope could easily be obtained. This arrangement would likewise provide for the flexibility of position previously mentioned as essential in such a structure in case of its being temporarily fixed by means of icebergs, &c. Also, in this manner any number of the mooring ropes would be prevented, seeing that the strain would be equally divided. Should it be taken up exclusively by the latter, the moorings would consist of steel wire ropes covered with tarred hemp, pitch, and tallow, for their preservation. Steel wire rope, two inches in diameter, of plough-rope quality has a working strength of about 17 tons, and each rope would weigh, including covering, 20 tons per mile. Assuming that only one mile deep in depth of water, 3 miles of rope was required, the actual weight of mooring-chains would be 60 tons, and the water displaced by them 60 tons, leaving a margin of strength of 120 tons for mooring purposes. A sufficient number of ropes to resist the strain or tendency of the structure to move could be used, and the proposed displacement of the floating bodies would be about 2,000 tons, and the author considers that there would be no difficulty in providing adequate moorings. The anchor blocks, to which the moorings are to be attached, would be constructed of rectangular iron plate and frame vessels, similar in build to sea-going vessels, with light decks, and being provision for admitting water to the interior. Each vessel would be loaded with a mass of concrete or stone into the lower part to the fullest extent which would permit of its being towed at sea with safety.

In putting down one of these lighthouses, it would first be necessary to make a careful examination of the ocean bed, so that rocky projections, obstacles, or bad ground likely to injure the mooring ropes could be avoided. Suitable foundations for anchorage having been determined upon, the anchor blocks would be towed out and placed over their intended positions. To diminish, as far as possible, the risk of their dragging or breaking the cables, it is proposed to deposit them in the following manner. After being securely and duly connected to the block, the rope would be laid out for a distance exceeding the depth of the ocean, so as to have a bight on the bottom between the ship and the anchor block. The latter would then be allowed to sink as gradually as possible by admitting water through a comparatively small hole. It is suggested as the most economical plan for erecting the lighthouse, that it be put together in sections, and conveyed to and completed in the shipbuilding yard, with the sealskelp portion in place. A heavy cover would be fitted to the lantern end, and the sea-light doors to windows and openings would be screwed on securely. The completed vessel would be launched and towed to the site selected, and the ballast would be employed for the purpose of sinking it. It would be fitted with a view to resisting any strains which it would be likely to encounter when being towed in the same manner as a ship; but the author believes that little extra precaution would be required on that score. When in position, a valve arrangement for the purpose would slowly admit water to the ballast compartment, and the vessel would assume its erect position.

It now remains to consider the question of power for driving the necessary machinery, and the amount of force which should be carried. A steam engine (in duplicate) of 30 horse-power nominal horse-power would be supplied for working the electric light machinery, a syren log-horn, and a crane to lift the heavy weights, &c. Taking the longest working period at seventeen hours per day, and the consumption of coal at 2 lbs. per horse-power per hour, 25 horse-power would be required continuously for that time, 50 or 60 tons of coal would be necessary, assuming two pounds of coal per hour per horse-power per hour, and making due allowance for decreased consumption. The position of the vessel has already been pointed out, a space 7 feet in depth being reserved for that purpose, directly beneath the compartment containing the inhabitable packing. This would afford ample room for the coal, and, if more, as that simple accommodation for fuel could easily be obtained. It is to be observed that, as coal would be consumed, provision would be made to admit water to compensate the weight of water ballast to preserve the margin of floating power as consumption took place.

The author would now draw attention to the glaring defects in existing light-houses with regard to wind pressure. Experiments carried out at a velocity of 100 miles per hour exerts a force of 55 lbs. per square foot; in what is known as a great storm, the pressure rarely exceeds 25 lbs. per square foot. If, however, a force of 50 lb. per square foot be allowed upon the entire section of the light-tower, that section being taken of an average width of 25 feet, and a total height of 120 feet, giving an area of 3,000 square feet, equal in amount to 150,000 lb., or say 70 tons. Such a strain would not be more than momentary, and would be expended long before the elasticity of the ropes (due to curvature) had been taken up. It is to be particularly noticed that the sag of the ropes would form a most effective spring to check any tendency to oscillation caused by wind. Even granting, for the sake of argument, that such a wind pressure might be of some duration, the rope, as specified, would be sufficiently strong to withstand the strain; and beyond the margin of strength provided, the easing of the balancing strain of the opposite mooring would add to the available power of the rope sustaining the force of wind pressure. It is proposed to make the weight of the structure, including proposed load arrangement about 1,000 tons, of which the author is of opinion that a great deal more than one-half could be carried and placed on her as to withstand any wind pressure that could be imposed without any inconvenient inclination of the light tower. The centre of flotation is situated about 20 feet below water-line. The weight of the superstructure, or lighthouse proper, is calculated at 300 tons, and the base portion at 700 tons, giving a difference of 400 tons. As the centre of this difference is situated about 70 feet below water-line, a wind pressure of the amount named would cause the structure to assume an angle of about 10 degrees with the perpendicular, as shown on the diagram. This has been calculated by the rule, that "the force necessary to incline a floating body through any given angle is equal to that necessary to raise it bodily through a height equal to the difference of the vertical displacements of the centre of gravity, and that of the immersed part," inertia and fluid resistance being neglected. The time of oscillation of the lighthouse, which, as well known, should not be equal to the periodic time of a wave, would be the same as that of a compound pendulum suspended from the centre of flotation, and would be four and a half seconds. The moment of inertia would be so adjusted that this time of rolling might not coincide with the period of any waves likely to be met with. Should it be deemed necessary that the tower should incline but under any conditions of wind pressure, deviate from the perpendicular pasture or take a pendulum motion, the wind would a twist exerted by the sails, and from to in suspension surface of the tower further to render all the fixed and rolling motion more easy. A cylindrical case, outside circumference fitted to the bottom of the immersed portion would effect this object. But the author is of opinion that both these provisions shown on the diagram are just needed, that the form of the structure, any extraneous contrivance, but being a reasonable or slight motion producing no discomfort to the inmates instead of the successful working of a deep sea lighthouse.

In conclusion, the author also proposes to employ similar light-houses on a smaller scale for coast service. The immediate saving of life and property around the shores of the United Kingdom alone, which would result therefrom, would be sufficient in one year to recoup their cost many times over.

THE PILSEN, JOEL, AND GATEHOUSE SYSTEMS OF ELECTRIC LIGHTING.

It is now just two years since we described and illustrated the Joel system of incandescent light, and rather more than one year since we did the same with regard to the Pilsen arc light. Since then several modifications have been made in both systems, and they are now being introduced to the public under the respective auspices of the Pilsen, Joel, and General Electric Light Company. The Pilsen lamp has undergone a complete change in its regulating mechanism, the latest arrangement of which are illustrated in the engravings at pages 286, 287, and 290 of our present issue. The Joel lamp, with regard to the Pilsen arc lamp, we may observe that it carries the same principle of regulation as the Pilsen, differing only in the construction of the mechanism. Fig. 1 of our engravings is a diagram showing the electrical construction of the Pilsen lamp, the principal feature of which is the use and action of a biconical or spindle-shaped iron core when suspended between and partly through the interiors of two magnetic solenoids, M, M', placed one above the other, through the coils of the electrical current is passing. When at rest such a core has no positive or balanced position, and is free, and will remain in any one position. The uniform action of this peculiarly-shaped iron core is due to the fact that the magnetic force of the solenoids which appears to be strongest at the centre of each, and which exerts a pull of less in one solenoid being compensated for by that of the other, and the magnetic pull of the solenoids is equal and vice versâ. Turning to the details of this lamp, we observe that the top coil, M, is in the main circuit, the negative wire after passing round this coil, being connected to the contact gutter, refer, and from thence through the frame and tube to the top electrode, and to the positive wire. The current passes from the bottom through the arc to the positive. One end of the sheet attached to the bottom carbon-holder, is connected to coil, M', of the wire and the other end of the wire of M at the terminal at top, the other end of the wire of M at the terminal connected to the bottom arbon-holder. The iron core, or dual bicone, which acts between the two coils, has another bevel tube, round which the cord passes, and from the iron core being counterbalanced by the weight, W, suspended from a pulley over the pulley, it, so that the core is free to move up or down to any position. The two coils, M and M', are regulated that, when the are formed at the carbons is of

£4 to £8 5s. 6d. The finished iron trade of North Staffordshire is in a depressed condition, and it is a long time since the works were so badly off. In no branch, except that of heavy sections, which keep in active demand, are the mills occupied more than three days a time, and many others cannot do that with regularity. The great falling off in the plate trade seems to be largely due to the very low prices now being accepted for steel plates, and the temptation thus offered to boiler makers to try the latter material. The dearth of orders and the reluctance of buyers to purchase are causing prices to become weaker, and makers are in some cases almost glad to accept offers for immediate execution, to enable them to keep their plant running. Crown bars are now quoted at £6 to £6 5s. 6d. The hardware market cannot be said to have improved, and prices are about the same as last reported. Although tinplate works are fairly busy, values of common brands have reached an abnormally low figure. Good coke tins have been sold at Liverpool this week at 15s. 3d. for fair lines. The enquiry for steel rails continues brisk, India and the American Colonies, as well as some of our own railways, being in the market at present. Upcountry trade has been advanced about 10s. per ton, but as yet buyers do not seem very willing to pay the increased prices. The shipbuilding trade is as unsatisfactory as ever, and a cessation is approaching on the wages question, as shipbuilders are giving notices all round for a reduction of pay. Enquiries for new ships are very scarce in all the shipbuilding centres. Engineers are receiving more orders than lately.

THE FOREIGN IRON TRADE.

There is no change to note in the condition of the iron markets of the Continent. Although, in consequence of stock-taking and the usual quietness at this season of the year, there is less enquiry in the Austrian iron markets, business must be considered on the whole satisfactory, whilst prices maintain their present firmness. The Belgian iron markets remain dull, with no prospect of improvement. There has been a slightly better demand for building iron at Charleroi, but competition is so keen that prices are not very low. The greater firmness in the French iron market, noted in our last, continues. Quotations are well maintained by the manufacturers of the Nord and Haute-Marne. At Paris merchant iron is sold to consumers at 165 *fr.*, and trade is active. In the Haute-Marne, coke iron is quoted 175 *fr.*; and mixed brands 165 *fr.* The better tone in the German iron market is maintained, and prices have gained in strength. The firmer tendency of English pig-iron during the last two weeks at home has been reflected in Westphalia, where it is found impossible now to buy it at the lowest rate previously quoted. The American iron market maintains its improved tone. In American pig-iron a better business is doing at unchanged prices. South pig-iron is firm, but the demand is light.

THE BRUSH ELECTRIC SYSTEM.

THE INCANDESCENCE LIGHT.

We recently described and illustrated the arrangements of the Anglo-American Brush Electric Light Corporation, whose offices are in the Belvedere Road, Lambeth. We now proceed to give particulars and illustrations of their incandescence system. In the engravings on pages 88 and 89 of our present issue, fig. 1 is an elevation of Dr. Victoria dynamo, which type of machine has been specially designed by the Brush Corporation for use in incandescence installations. The armature of this machine is built up of thin laminated wrought iron plates, which radiate to a milchrome iron core, whose ends are iron ring, while between the plates are intervening air spaces, thus allowing of perfect ventilation of the armature when the machine is at work. The wire on the armature is wound continuously; that is to say, the end of one bobbin is connected to the inside end of the next contiguous bobbin, and of those two wires being connected to the same segment of the commutator. The field magnets, by which there are four, alternate in polarity in the plane of the armature's rotation, and indium cores are introduced into the armature, which are conveyed out at the commutator. It will be noted from the illustration that, although the magnets are four in number, only two pairs of leading conductors are required. This is effected by means of an ingenious method of connection, which consists in coupling the diametrically opposite sections in the ring, which are entering a field of positive polarity simultaneously, while that of the sections traversing opposite portions of the armature in the same direction are collected as a single current at the commutator, instead of at two, as might be expected.

Figure 2, of our engravings, represents the M. Victoria machine. This, it will be observed, is of a somewhat similar type to the foregoing, and is constructed upon the same basis, but has double the number of poles, and consequently double the number of bobbins only of considerable size. The dynamo is stated to be capable of maintaining 1,000 incandescence lamps or 10,000 light lamps. Designed for the latter class of lighting direct, these machines are, however, admirably adapted for battery-charging purposes, to which branch the corporation has attached considerable importance. These machines may also be effectively used as motors, and when used in this form they return a high percentage of the power delivered to them. The Victoria machines, when arranged for battery charging, are wound with their magnets on a shunt, whereas in cases where the incandescence lamps are to be run off the dynamo direct, the machines are in most cases compound wound. For search-light work the dynamos give good results, the compound winding almost entirely obviating the strains to which the dynamo and engine were subjected by the contact or alteration in distance between the carbon points, and at the same time assisting in maintaining an arc at a constant length.

Fig. 3 represents Allen's hand regulator for the incandescence system. Fig. 4 illustrates an automatic regulator for use with incandescence lamps, in cases where a compound wound self-regulating dynamo is not used, and fig. 5 its accompanying contact maker and break. The action of this apparatus may be briefly described as follows:—A pair of magnets in the base of the frame control a clutch movable upon a feather on the spindle, shown in fig. 4, this spindle being kept continually revolving by means of a band or gut from any convenient countershaft, or directly from the shaft of the dynamo. These electro-magnets are controlled by a small galvanoscope, shown in fig. 5, the solenoid being placed on a shunt circuit across the lamp circuit, the core responding in one direction or the other as lamps are turned on or off, its action being to direct the current in the magnets at the base of the regulator, and thus vary the resistance in the magnet circuit of the machine, by causing a clutch in connection with a worm and wheel, to increase or diminish the pressure between a series of carbon resistance plates. In this way the incandescence light is rendered as entirely under the control of the user as any other form of illumination. Those requiring any number of lamps, driven off one or more machines, do so without any affect the remainder.

We need hardly point out that the incandescence lamp effects the subdivision of the light in a very satisfactory manner for domestic purposes, and while giving a light of beautiful tone, it relieves the air of the atmosphere. Also in factories, workshops, breweries, mines, and all places where large lights are a considerable source of danger, on account of the presence of inflammable materials or explosive gases, the use of this lamp must obviously recommend itself, owing to the fact of the filament being entirely enclosed within an air-tight globe, the fracture of which instantly extinguishes the light. The lamps manufactured by the Corporation range from 2 to 25 candle power, and may be briefly described as follows:—The globe, which is either of clear or frosted glass, contains a horse-shoe shaped filament of carbon, rendered incandescent by the passage of the current. Through one end of the globe two platinum wires are sealed, to the inside ends of which the carbon filament is attached, into a loop, and fused into the globe. This arrangement prevents fracture of the wires at the point where they enter the globe, which is very apt to happen where the lamp is exposed to vibration or constant handling. Figs. 6 and 7 of our engravings shown ordinary incandescence lamp, fitted ina socket as is rendered for electrolysers or for screwing on to gas fittings when the burner has been removed; and fig. 8 a similar socket with an attachment for fixing to gas brackets, without removing the gas burners or interfering with any existing fittings. The two branch wires coming from the main are carried through the bottom of the socket, and secured under screws, which are in connection with two springs within the socket. The lamp wires pass through the cap and are secured under the two screw heads shown at the bottom of the cap in fig. 6. When throwing into circuit, or replacing any lamp, all necessary connections are instantly made, by simply introducing the capped lamp into the holder, the screw head on the cap pressing against the spring within the socket, and the lamp at the same time being firmly held in place by means of the plain projection on the side of the cap, which is pressed into two slots in the socket or holder. Fig. 9 illustrates a wall or table socket intended for use in localities exhibi, to movable tables, or other lamps. The socket is fixed flat against the wall or table, and the lamp would be required; the holder illustrated, to which reference has been made, is screwed on to the socket, the other is connected to the lamp, can be removed from the socket, and used as a hand lamp. The top portion of the room, where a similar socket is fixed, the necessary connections being made by simply introducing the holder into the socket, and giving it one quarter of a turn. An ordinary switch is introduced into the circuit, for the purpose of removing the deadly safe holder.

We now come to those useful and important accessories of every system of lighting, known as switches and distributors. Fig. 10 is a view of a switch suitable for one, two, or three lamps. This switch has been designed with a view to meeting the requirements of the fire insurance companies, and has received the approval of the fire risks committee, appointed by the Society of Telegraph Engineers and Electricians, and they are so arranged that it is impossible to leave the contact pieces in an intermediate or half-way position, while an efficient contact is secured by means of a spring between the two metal surfaces firmly together. An efficient and simple wall switch is thus obtained. The Bipon switch, which has a similar safety arrangement to the preceding one, is made of the size and appearance of the small tap on a gas lamp, and can be conveniently used in the same position when replacing gas jets by incandescence lamps, using the same fittings. There are also reducing switches for varying the brilliancy of the light, by the employment of these, the user is enabled to obtain any desired degree of illumination up to the full power of the lamp, as the simple movement of a handle introduces into the circuit of the lamp a resistance which varies with the position of the tap, and maintains the light at any required brilliancy. Figs. 11, 12, and 13 represent three designs of safety cut-outs, being besides these are many other forms, in order to avoid any chance of the undue warming of the wires, a piece of wire, fusible at a very low temperature, is inserted into the circuit. The Corporation have secured, through Messrs. Johnson and Matthey, a fusible wire, possessing very remarkable properties, which have been arrived at by special mechanical treatment of a new alloy, and which has the exceptional advantage of breaking off short without first bending so soon as the temperature of fusion is reached. This temperature is a very low one, far below that of boiling water, it therefore melts long before the temperature of the cables become appreciably raised, and by reason of a break in the circuit, prevents the current from flowing in that particular branch or portion of the circuit. Fig. 14 shows a switch suitable for a single lamp, fig. 12 one for six lamps, and fig. 13 one for ten or twelve lamps. Fig. 15 illustrates a time switch, which is an arrangement whereby a consumer may have one or more arc or group of incandescence lamps on his premises turned off at any desired time. This is effected by setting the clock, as in an alarum, to the hour at which it may be determined to extinguish the light, when the switch, shown at the top of the figure is automatically thrown out of contact with the wires, while a series of dials at the base of the switch registers the number of hours during which the lamp or lamps have been burning. The clocks in use are such as are employed for various qualities which would be suitable for use in offices and public halls of admission, or would call attention to the compound wound dynamos supplied by the Corporation. These machines are self-regulating, it being possible to turn out any number of lamps, from one without affecting the remainder. The efficiency of the machine is also stated to be very high, it is larger since 96 per cent. of the mechanical energy of the belt being transferred into electrical energy, and 88 per cent. of the same appearing as useful work in the outside circuit. By the use of these compound machines the consumer is enabled to switch off any number of lamps supplied by the dynamo, the increase power required remaining practically proportional to the number of lamps in use, while the necessity for any external appliance for automatically regulating the dynamo to varying loads is dispensed with. On the whole, it will be seen that the Brush Corporation have two excellent systems of electric lighting, and it is satisfactory to know that both have proved that they have two in London—are kept fully employed in turning out machinery and apparatus for new installations.

Occasional Notes.

SILVER IN AUSTRALIA.

Native silver does not appear to have been found in any quantity in New South Wales. The Rev. W. B. Clarke mentions the South Sea Company's claim, in 1830, that silver had been met with in the southern districts, and also specimens of silver in the form of small fragments and atacreous crystals. Count Strzelecki mentions the occurrence of native silver on Mount Kosciusko Range, from Piper's Flat, in New South Wales, in 1839, and says that native silver, native nickel, and native spangles is disseminated in primitive greenstone, and deserves further examination. Native silver also occurs also in the Hocrock Mines, with the chloride, sulphuret, and ruby silver; and at Carlton, Illawarra, Bungay, Hunter, and Manley Districts; and Worrell Creek, to the north of Liverpool. A small plate of native silver found by Mr. C. Sutter, junior, in the quartz of a vein containing galena on the Mount Grenville Estate, near Bathurst. The Australian silver-mining industry would have probably developed if undertaken by parties really possessing the knowledge of separating the metal economically from the ores with which it is generally found in combination. In a recent report of the New South Wales Department of Mines, it is stated that, at Nundumbeah and Umbersnicks, near Mount Gipps, in the Albert District, extensive deposits of silver and lead ores have been opened up. Large quantities of the ore are found as and

BRUSH ELECTRIC SYSTEM.

IRON.

THE PRACTICAL APPLICATIONS OF ELECTRICITY.

The question of the application of electricity to the illumination of our streets and public places, as well as of the interior of our dwellings, is just now in a transition state. From the stage of huge admiration and amusement easily, if sometimes successful, experiments, it is passing to that in which its practical utility is an accepted substitute for gas will be measured by the only ultimate test—permanent adoption by the general public as its chief illuminating agent. So long as the electric light remains a hobby in which only the wealthy can indulge, or so long as its use is confined to some isolated places or buildings, it cannot be regarded as anything else than a costly toy; and as it be admitted that the predictions of its advocates have even approached verification. The *furore* which was created about twelve months ago assisted, and at the same time damaged, the cause of electric lighting; and it is to be feared that the damage preponderated greatly. While abundant capital was placed at the disposal of the new illuminating agent—in itself a matter of congratulation—the stock exchange gambling which was fostered, and which led to the search for spurious profits by the sale of patents, and by the introduction of numerous bubble companies whose very existence differing, however slightly, from its predecessors' could be got hold of, could not fail to bring a certain amount of discredit upon the matter. Besides this, an undesired currency was brought into prominence publicity, and the attention of those interested in the perfecting of it turned aside from the scientific to the commercial aspect of the question. The effect of these unfortunate circumstances has perhaps been a great measure passed off by this time, but some incubus will always remain on account of the losses some sustained in promotion money and in payment for worthless rights; and it must always be a matter for regret that legitimate enterprise should be so much at the mercy of unscrupulous men.

The action which the Government deemed it necessary to take last year, in view of the large and sudden importance which the question of electrical illumination had assumed, has interposed a further barrier, doubtless, in the way of the supreme attempt being made to attain practical results. But considering the interests involved, it must be admitted that such a step as the Government took was requisite, and that the delay which it has caused may have had a salutary effect in preventing immature plans and projects from being forced on to the public. According to the provisions of the Electric Lighting Act of 1882, the Board of Trade was empowered to grant licenses or provisional orders for electric lighting. The licenses were to be for periods not exceeding seven years, but it was necessary that the consent of the local authorities for the districts to which they related should be obtained, the local authorities having power to such consent to their assent as they considered expedient, subject only to the approval of the Board of Trade. For some reason, which is not very well understood, however, the latter have as yet been granted by that department. The provisional orders which the department was empowered to grant, might be for any period, limited or unlimited, but they have come to be looked upon as practically having the effect of restricting the enjoyment of the privileges conferred to a period of twenty-one years, owing to the clause in the act which entitles the local authorities to take in at the expiration of that term and take over the enterprise of the electric lighting company at its fair market value. The merits of this arrangement are open to criticism, as they were freely discussed in these columns at the time of the passing of the measure; it is unnecessary to refer to them further at present. It is not to be wondered at, however, that, under the circumstances, the number of applications for provisional orders which have been lodged by local authorities has been comparatively trifling. Out of 106 such applications received by the Board of Trade up to December 31 last, only twenty-three were promoted by local authorities, the remaining eighty-three having been made on behalf of companies. The provisional orders so granted by the Board of Trade numbered twenty-seven, but of the number of these have been before the public for some time, we may look at no very distant date for the first attempts at the practical application of, electricity to the lighting of large districts for domestic purposes as well as public. The result of the first experiments will be watched with keen interest.

But it would be well for all concerned in the electric lighting companies, shareholders as well as officials, not to be too sanguine as to the results, at least in the immediate future. Even if the success of the systems before the public at present were incontestible, there is a great *vis inertiæ* to be overcome. People have got accustomed to gas, and, with all its drawbacks, it is an illuminating agent easily used; and, moreover, thanks to the agitation occasioned by the electric light, the quality has latterly undergone considerable improvement, and, in London at least, the price is moderate. The gas companies have, in addition, got a long start of the electric light companies, and will make a desperate fight before they allow themselves to be beaten off the field. So much for an authority as Captain Douglas Galton, while expressing his opinion that electricity as an illuminant in large will ultimately supersede gas, has stated that the new methods of gas lighting which have been introduced bid fair to retard the universal adoption of the electric light for domestic use. It is probably upon the question of cost that the ultimate decision will turn. To be a practical success, electric lighting must be patronised by the general public, and the greater part of that body will judge how it pays from question of price. No matter what purity of atmosphere or other beneficial effects be set down to its credit, unless the price at which the companies can supply it is such as to induce the general public to adopt it, it is difficult to see how it can be rendered a financial success. So far as experience has gone yet, the electric light cannot be supplied at a rate to compete with gas, and when this is the result of competitions where gas is comparatively dear, it follows that in London, with cheap gas, the level price at which the electric light will be placed is still greater. It is noteworthy circumstance that the company, started last year with a most influential board of directors, for the purpose of taking up and working any feasible system, has been wound up, the shareholders declaring that, although they examined numerous schemes submitted to them, found no one which was practicable. In short, there was no work for the company to do. The shareholders have in this case been very more fortunate than we fear those in most companies connected with electric lighting will find themselves, the capital having been returned in full, as the interest earned was sufficient to cover expenses.

In considering the subject of the practical applications of electricity, we have naturally referred first and at considerable length to its use as a illuminant, since it is that matter that it has been principally before the public of late; but there are other directions, in which great efforts are being made to apply it successfully, which demand a brief reference. Perhaps next to lighting by electricity, the propulsion of tramcars by its agency has occupied the greatest amount of attention on the part of experts. But although great energy and perseverance have been devoted to the matter, they have as yet failed to bear any practical fruit, the great difficulty being to avoid the danger to horses where the rails are used as electrical conductors, and to provide against the interception of the current by the other traffic on the same road. On account of these difficulties, an electric railway would appear to be more feasible than an electric tramway, but it is open to question whether scientists will ever be able to develop sufficient power in electricity to make it adaptable to

authorities has declared against the practicability of it, and, without doubt, the remaining eighty-three accumulators, has ridiculed the idea of hauling carriages with land in order to assist in making them move. A revival of an old idea in the application of electricity has been recently made by employing it for the propulsion of small launches. There is no doubt that there is a field for it, and although it would be premature yet to predict cutting out steam, the advantages which the use of electricity offers in this case are such as to augur well for its ultimate achievement. In short, Sir Isaac Holls also we would not have it thought that we consider the prospect as hopeless, but there can be little doubt that considerable patience and perseverance will require to be exercised.

Iron, Aug 4, 1882.

THE MUNICH ELECTRICAL EXHIBITION.—In connection with the forthcoming electro-technical exhibition in Munich, Baierische Kunstgewerbe-Verein has announced a competition for light-fittings (lustres, brackets, candelabra, &c., suitable for the electric light. According to *Nature*, the Edison illuminating, to be maintained by about 8ohorse power, will be no way inferior in extent to that in Paris; the engineering will principally consist of a double line of wires in the streets, and the theatre, will be lit with 800 Edison lamps. The Exhibition, which will be held in the Glaspalast, Munich, is now open for centrally lighting up a whole city quarter with 12,000 lamps and 12,000 test candles. Mr. Schuckert, of Nürnberg, is to be tried in New York. Palace light up the Crystal with a reflector lamp of 10,000 candle-power; also the engineer's theatre with an upper light of 2000 candle-power. There will also exhibit several transportable electric lights for use in mines, and ways, &c. Special interest will attach to that to utilise the water-power of the Elsbachen, about three miles from the palace; the current will work a lift, or hoisting machine, in the palace by day, and illuminate the garden and the Kunstgalerie by night; 24 lamps of 1000 candle-power each. The copper wire will be 3 mm. thick. A monitorial account of the exhibition is supplied with the *Elektrotechnische Zeitschrift* for July.

MARCH 31, 1882.

IRON.

THE LORELEY BY ELECTRIC LIGHT.

There is every probability that the electric light will soon find an application hitherto not thought of. The steamboat company plying their vessels on the Rhine and the Lake of Constance have recently made experiments with the Bürgin lamp, placed on board a steamboat, by which it is possible to satisfactorily light up both shores of the river ahead on the vessel proceeds on her course. We quite recently illustrated in these columns an arrangement by which the paramount way may be lit up for a considerable distance ahead by means of a reflector placed at the stern of a steamer, driven by a motor placed on the platform of the engine. Now, what is practicable in such a position, exposed as the whole apparatus must be to constant oscillation, is equally easy of attainment on board a vessel. The vibration and thumping experienced on board a steamer is considerably reduced in intensity, if it does not wholly disappear, at her head. We also have seen that all be anticipated if the successful experiment carried out on the Rhine will lead to the adoption throughout Germany by the steamers running on it. Travellers by that delightful route will then have their enjoyment heightened by the beautiful effects of the electric light, which will add fresh charms to scenes which, once seen, engender in the traveller the desire to again and again taste of the joys which a trip on the Rhine affords.

MARCH 31, 1882.

IRON.

THE VIENNA ELECTRICAL EXHIBITION.—The applications of electricity are so numerous, and are so universal, and give it a thoroughly international character. From the published lists it appears that, leaving Austrian exhibitors here, there are representatives from the United States, Belgium, England, France, Germany, Italy, Russia, Sweden, and Switzerland. We are further informed that the time for receiving applications has been extended to March 20, by which time the plans will be handed in to the secretary of the Society of Telegraph Engineers, 4, The Sanctuary, Westminster. We are also authorised to state that the committee at Vienna are making arrangements for a reduction in the rates of transit on all goods forwarded to Vienna for exhibit on.

THE ELECTRIC LIGHT AT THE VIENNA EXHIBITION.—We learn that the executive committee of the exhibition have recently come to a decision to light their grounds by electricity, and that they have already made arrangements for the illumination of fifty two-light sets of lamps. Messrs. Davey, Paxman, & Co., so well known for the excellence of their engines in connection with the electric lighting they have undertaken, as most favourable terms, supply us a necessary motive power, which has been calculated at more than 600 horse-power. There will be four engines, one of which will indicate 200 horse-power. We consider this to be the greatest honour paid to any engineering firm in this country at the present time, and we feel sure that we may say the same of the engines and appliances about to be used. The principal men who will superintend the engineering engagements would prevent their presence in the daytime.

THE MANCHESTER ELECTRICAL EXHIBITION.—An electric lighting, gas lighting, and general engineering exhibition was opened on March 25 in Messrs. Heaton's Hall, Manchester. Notwithstanding the efforts of the promoters, the exhibition is not yet in complete order, and some time must yet elapse before many of the more interesting objects of display will be seen in operation, or exhibits in position. Under these circumstances, therefore, it is impossible to enter into details, but we may say that the engines and appliances about to be used. The principal men who will superintend the engineering engagements would prevent their presence in the daytime. The Manchester Electrical Exhibition

Fig. 3.

Iron, Feb. 16, 53.

floors and incidental work, £60 ; engine and boiler, extra flywheel and belting, £360 6s. ; counter-shafting, £25 ; foundations to engine and floor-laying, £40 ; erection, laying and brackets, &c., £205 18s. ; total, £1,470 8s. The cost of the first outlay for electricity is a will be seen, somewhat in excess of the amount for gas; but there is no suffocation of gas into the house, no smell in the manufacture, or damage to garden ; and, in the case of an unsightly encumbrance, Mr. Coope has a compact little engine, placed out of view, and which, when not driving the dynamos, is utilised for pumping water to the top of the house, and can also be employed for sawing wood, or any other purpose of a like nature required.

In estimating the annual working expenses, and in making a comparison, Mr. Coope assumes that it would cost the same to manufacture 1,000 cubic feet of gas at Bochetts as it does at Rochetts. The electric light – 200 16-candle lamps, each working 1,650 hours per annum at 50s. per week, 478 ; renewal of lamps, 120 at 2s. each, £38 8s. ; depreciation 10 per cent. value of machinery, £74 ; depreciation 5 per cent. on engines, £4 Total, £232 18s. 4d. Now for less than half this amount of light it costs Mr. Coope £200 a year at Rochetts, and he is, therefore, if anything, understating the expense when he says that, half he used gas at Herschrede giving an equivalent illuminating power, it would have cost him at least £400 per annum to produce. This would show an annual saving of £167 4s. 11d. to him by using electricity. Having had twenty years' experience of lighting Rochetts by gas by a system which he considers a great improvement upon its drawbacks, and, although he is fully too sensible of there yet, he is well satisfied that he has adopted electricity at Herschrede.

The above very clear statement, however much its details may be disputed, is, as already remarked, unmistakably in favour of the electric light ; but it fully bears out Dr. Siemens' view that the latter is at present only a luxury to be indulged in by the rich. We must, however, speak with Dr. Siemens again, and be satisfied with his old friend—gas, and bear with him a little while longer. Electric light companies, however, whose success depends upon their ability and willingness to supply the general public with a cheap light, ought to pay more attention to the commercial aspect of the question. For reasons best known to themselves, but pretty correctly guessed at by world-be consumers, they put such a price upon the commodity which they wish to dispose of as to make its superity nearly prohibitive. An instance that just came under our notice in which a company, which shall be nameless, offered to supply the electric light at at least three times the cost of gas. It is absurd to suppose that under such conditions the electric light can make headway. It is still more foolish to expect the public to pay extravagant rates for what they can very well do without.

THE ELECTRIC LIGHT AT ALEXANDRA.—Messrs. Allen Alderman and Co., of this city, who have worked the electric light at Ranelagh for the last month, have received £50,000 grass from the Alexandra Park Company. The Alexandra Park Company, which is a limited liability company, has already exceeded the fees of last July, having been expected to do only £40,000 gross. The public benefit, too, has been the great service in supplying H.M.'s troops with various marching orders. The machine used is a Gramme of twelve horse power. The Savoy lamp belonging to the machine is the Crompton. It has been in use for a long time, and is now being made for 2,000 candles. The lamp which is in it is fully expected, three times as large as at present. The Gramme machine is coupled to a portable engine manufactured by Messrs. Rustin, Proctor and Co., of the Sheaf portable engines for pumping out the old cisterns, and this little machine of Messrs. Rustin and Proctor's has been pumping salt water from the sea, near the Ramleh station in town, and feeding the water up to a place close to the Ziania Theatre for the purpose of flushing the town drains.

Journal Jan. 5, 1882.

Iron, March 2, 1882.

THE CHAMBERLAIN LIGHT.

A new process of gas manufacture has recently been brought under our notice, in which oil, water, and air are the three agents from which the gas is produced. This process is the invention of Colonel Chamberlain, and the product is a gas of high illuminating power, and, of low cost, two very desirable qualities. The apparatus consists of a cast iron retort, which is placed within a coke furnace, so arranged that the heat from the furnace passes the retort is conducted to the flue without coming over it. The oil—which is the best quality of petroleum—is stored in a small tank, the water, being stored in the another purpose. From the tank the oil and the water are led by pipes—the former of oil at one-eighth of water—into a small vessel where they unite, and through which they are regulated by stopcocks. In this latter they are discharged in the constituent gas passes away through a pipe of larger diameter to a washer. The mixture of a cubic foot of cast iron, having vertical dividing plates, and being partly filled with water. The gas passes underneath these plates and through the water to the gasholder, where it is stored for use. In the washer is deposited a residue which is found to contain a useful lubricant and a material for staining wood, besides yielding lamp-black. The gas so far is only a product of oil and water; the third constituent—air—has yet to be added. This is forced into the retort by means of a small Roots blower, and there decomposed. From the retort the air flows into the washer and the gasholder, and picks up on its way, much of the oil-gas as may have escaped from the retort, the retort or the washer. The air is added in the proportion of 3 of air to 1 of the gas already mentioned in order to be of 21-candle power, and to cost 1s. 3d. per 1,000 cubic feet. It is stated to be of 21-candle power, and to cost 1s. 3d. per 1,000 cubic feet. It is stated that experiments have been conducted by gentlemen connected with the Board of Trade, which have proved the gas to be of great illuminating power, and of low cost. In one of these experiments it has been found that it is a good, light, steady, permanent, and travelling gas, suitable for dwelling. It is reported to be free from smell, humidity and deposit, and of such a nature that during storage under various conditions its illuminating power remained at a maximum, whether the gas was subject to the chemical properties change. It is moreover said to contain no sulphur, and only a trace of carbonic acid. It gives an excellent light, as was demonstrated on our recent visit to the Lower Belgrave Street, Pimlico, where a working apparatus has been at work for some time past. The good features of the gas were for the most part demonstrated, the gas being rapidly made, and giving an excellent light by the customary cause and is very highly reported of also being clearly distinguishable. Its cleanliness and the absence of carbonic acid were apparent from the general appearance of the room and of the flowers and shrubs in it, which had been subject to the influence of its light ; and the latter also for some time past without any deleterious effects being made visible. The generator measures about 3 feet square in plan and stands 4 feet high, and is capable of the production of 70 feet of gas per hour. A saving of 25 per cent. is said to be obtained in the consumption of coke, 30 per cent gas, 770 cubic feet burning as long as 1,000 cubic feet of ordinary gas. It will mix with coal gas, which it is said it will enrich. It will thus be seen that the Chamberlain light possesses many advantages which commend it, for use wherever the ordinary sources of artificial light are either too dear or unobtainable. Having regard to this fact, and to the circumstance that with it is very easy to manufacture, we do not see why it should not meet with a wide adoption.

Sept. 22, 1882.

THE MUNICH EXHIBITION.—A series of electro-technical experiments on a larger scale are now taking place at the Glaspalast exhibition in Munich. Their object is to give general public, a number of scientific authorities, as well as the electricity in its practical shape, a survey of the present state of electric transmission of force, particularly with reference to the application of electricity to lighting purposes. It is expected that these trials will tend to propagate the introduction of electricity both in public and private life, to the great benefit of the community at large.

THE CROMPTON ELECTRIC LIGHT.

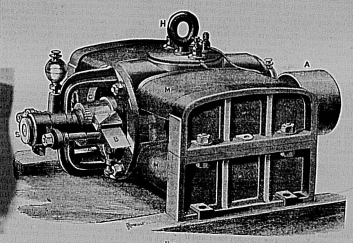

Fig. 1.

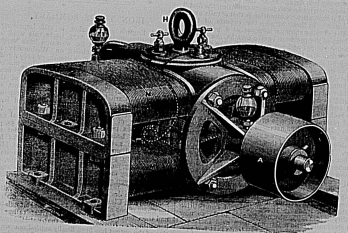

Fig. 2.

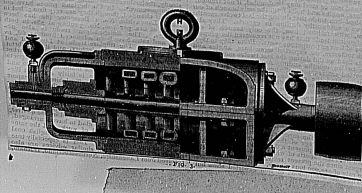

Fig. 3.

The iron markets of the Continent preserve their former firmness. In the Austrian market quotations are becoming much stronger, consequent upon the greater demand for both pig and manufactured iron and steel rails. The tendency of the Belgian iron market has not changed, the demand continuing active, and prices firm. With work assured for a couple of years ahead, the French iron trade has attained a position which nothing but the most extraordinary events could well disturb, and as, as a matter of fact, nothing is likely to happen which could have such an effect, its prosperity for that length of time may confidently be predicted. It is fully expected that a rise in quotations in the German iron market, which are at present extremely firm, will soon take place, partly in consequence of the slight advance secured in the prices of coal. Hoerde pig has already risen 5 marks, and is now quoted at 45 marks per ton. The approaching winter and the great briskness of the iron trade has infused fresh life into the coal markets of the Continent. Advices telling almost the same tale are received from Austria, Belgium, and France, where quotations have a rising tendency, which before long will find it mightier expression in higher prices. The German coal trade is proceeding steadily towards improvement, and rates are very firmly maintained. The Silesian coalowners having raised their quotations from 9d. to 1s. 3d. per ton, the advance to take effect from October 1, a German writer computes that, if their example were followed and the higher values maintained throughout Germany, the increased income would be between £1,250,000 and £1,550,000 per annum, a sum large enough to improve at once the wretched position of the mining population and ensure owners a fair return for capital sunk. The American iron market has become much firmer, Scotch pig-iron is rising in value, Gartsherrie being now quoted at $24. From the returns issued by the United States Bureau of Statistics for the fiscal year ending June 30, 1881, it will be observed that up to that date a very decided decrease had taken place in every item of the iron and steel imports into the States, except iron and steel rails, the imports of which have more than doubled. The values represented by the iron and steel imports were $60,144,611 for the year ending June 30, 1881, and $70,037,771 during the same period in 1880, thus showing a falling-off of over $10,000,000. But as last year was quite an exceptional year in our commercial intercourse with the United States, the imports in 1879 amounting to only $29,926,665, we have every reason to be satisfied with the trade returns for the current year, more especially as the demand from the United States has steadily increased since the date at which the statistics referred to were compiled.

THE CROMPTON ELECTRIC LIGHT.

We recently recorded the successful lighting of the King's Cross Station at the Great Northern Railway by electricity; the system employed being that of Mr. R. E. Crompton, of Mansion House Buildings, Queen Victoria Street, London. We now have the pleasure of placing before our readers illustrations and a full description of this system, including the new circuit lamp recently perfected by Mr. Crompton. The current is produced by means of a Mergin dynamo machine, which was invented by C. E. Mergin, of Aarau, Switzerland. The original machine was designed for a single light; it is, however, due to Mr. Crompton's improvements that a greater electro-motive force is obtained, which renders the machine capable of supplying several lights. It is a very efficient machine, whilst at the same time its portability and small cost are greatly in its favour. The machine is illustrated in the annexed engravings, in which fig. 1 is a view of the commutator side of the machine, whilst fig. 2 shows the other side of the machine with driving pulley. Fig. 3 is partly a longitudinal section and partly a side elevation, and fig. 4 corresponds to this in transverse section, whilst fig. 5 shows the armature. The machine is a ring-wound machine, that is to say, that the coils of the armature should have a high surface velocity, and with the ordinary Gramme ring this is impossible on account of the wires of the coil being so closely confined and so thickly wound as to make them very apt to heat with the current; but the coils of the Mergin ring, being composed—as will be seen on reference to fig. 5, which represents the armature of a three-light machine—of several separate rings, R, attached to the spindle, S, so as to form a kind of cylinder, go all away with the chances of heating; the sections of these rings are connected in series to the sections of the commutator, and the current is then collected by copper brushes in the ordinary way. The armature consists of a circular loop of the Gramme, each core is a frame of soft charcoal wires built up into a square bar. After covering each side of the bar with varnished tape, a coil of wire is wound on, passing the iron corners of the core bare, and the coils are arranged so as to make the general outline circular. This arrangement is shown in fig. 5, R is the ring; C the bare corners; and W the wire coil. It is obvious that a highly magnetised state of the core is obtained by passing so many bar poles of the core close to the poles of the inducing magnets.

IRON.

ELECTRIC LIGHTING AT THE FISHERIES EXHIBITION.

ALTHOUGH the electric light as a commercial agent at the Fisheries Exhibition have been completed and in operation for some time past, it is only somewhat recently, by reason of the shortening days, that the bulk of the visitors have been enabled to see the illumination at its best, and to fully appreciate its excellences. Therefore, it is now in full and perfect working order, we suppose to place practically similar to that installation before our readers. When the magnitude of the exhibition is considered, the extent of the electrical display, necessary to properly light it up will be approximately understood. It cannot, however, be fully realised without a personal inspection, but, as following its extensive features, we may mention at the outset that the total illuminating power is estimated at one million candles. The source of this immense volume of distributed light is a few collections of engines and machinery placed in an annexe 160 feet long by 60 feet wide, situated in the south-western angle of the exhibition grounds, and adjoining the machinery in motion annexe. Here are to be seen a number of engines by Davey, Paxman & Co., having an aggregate of 400 to 1,000 horse-power indicated, together with boilers for supplying steam by the same makers. Here also is a fine collection of dynamo machines by various makers, and which receive motion from the engines on the one hand, while, on the other, they give out that motion as light. The various electrical systems employed are for the most part well known to require description at our hands, so that we may now proceed to indicate before doing so, however, we may mention that there are sixteen firms who have not only engines, machines, or lamps individually, but all three.

Turning first to the motive power, we may observe that Messrs. Davey, Paxman & Co., of Colchester, have constructed and lent the six engines which are employed in driving the dynamo machines. The first of these is a fine double horizontal engine of 400 horse-power indicated, having cylinders 19 inches in diameter and 24 inches stroke, making 60 revolutions per minute. The second is a compound engine, of 250 indicated horse-power, and has cylinders of 15 and 24½ inches respectively, with a stroke of 2 feet, and making 120 revolutions per minute. There are also three double-cylinder engines of the semi-fixed type—that is, with horizontal engine and boiler on one bedplate. These are each of 125 horse-power indicated horse-power, there is a total of 1,135 indicated horse-power. The two large engines are fitted with Porter's patent automatic variable expansion gear, by means of which the speed of the dynamo machines may be minutely regulated, and with the result of giving the steadiness of light which will be noticed by visitors to the exhibition. In the new gear the cut-off valve is driven by a pair of eccentrics, the rods being connected by a link to the valve rods, being connected in the usual manner, which, in turn, are actuated by the governor. The cut-off valves are double-ported valves, two extreme positions of the link from end to end. The peculiarity of this gear is that the two eccentrics have different throws, the one which cuts the steam off early having a very short travel as compared with the other. The cut-off and exhaust slide valves are upon opposite sides of the cylinder, the exhaust valve being driven by an ordinary eccentric and having an invariable travel. The automatic regulation of the dynamo machines by the Paxman engines has so commended them to those responsible for lighting of the South Kensington Museum, that the largest of these engines has been bought for the duration of the exhibition, and after its period it will be moved across the road for permanent duty in the museum. Steam is supplied to the 400 horse engine from three Davey-Paxman boilers of the locomotive type, and to the compound engine by two similar boilers. The other engines of course have their own boilers connected to them. We may mention that the bedplate of the compound engine is of a new type, being formed of girders placed on their sides and upper surfaces. When bolted together they form a strong, neat, and economical foundation. This method of construction was resorted to in consequence of the difficulty experienced in finding a good foundation.

Messrs. Siemens Bros. & Co. are lighting the main gallery, containing the exhibition of British manufactures, by means of Siemens lamps, and the conservatory, adjoining the Royal Albert Hall, by their arc lights, each produced by a current of 32 ampères. The incandescence lamps in the main gallery have been supplied by the Swan United Electric Light Company, and give out a light of 20 candle-power each, with a current of 46 volts and 1?34 ampères. The gallery is 600 feet long, and its roof is supported by 80 wooden arches, each having 12 projecting points on which the holders for the lamps have been fixed. At the western end of the gallery fifty-one lamps have been placed in the three arches forming the entrance to the permanent building. Altogether, 1,040 Swan lamps are distributed over the gallery. The necessary current is supplied by two Siemens alternate current machines, and the leading wires are carried over the roof, so that lamps on alternate arches are worked by the same machine. It is also noteworthy that the lamps in all parts of the gallery burn with equal brilliancy, a result obtained, without any regulating apparatus whatever, by a suitable arrangement of the circuits. A Siemens continuous current machine produces the current for the arc lights in the conservatory, which are connected parallel, and are at a distance of about 400 yards from the machine. The lamps are of the ordinary Siemens pattern, such as are used with single light machines, and have no shunt regulating coil as required when lamps are worked in series. The effect of the incandescence lighting in the British section fisheries gallery is exceedingly pleasing. As seen from the eastern end, the long arcades appear to be closely studded with the glowing points of light. The Swan United Electric Light Company, of No. 8, St. Mildred's Court, Poultry, have illuminate the Royal Pavilion with 100 Swan incandescence lamps of 20 volts arranged in parallel series. The lighting is intended to demonstrate the adaptability of the incandescent lamp to decorative illumination, in which it certainly succeeds. In the conservatory this company have lamps of 20 candles light of 20 volts, which are employed to give coloured and shaded light and water effects. The chandelier lamps consist of the current to the high resistance lamps consist of the current to the high resistance lamps consist of the current to the high resistance

Exhibitors are not to pay any rent for the space occupied by their exhibits, and the general commission undertakes at its own expense the arrangement and general decoration of the building. Exhibitors, however, will be to bear the expense of the installation and decoration of their own exhibits, and the plans of these must be submitted to and approved of by the managing committee. Motive power will be supplied to exhibitors who require it at 20 kreuzers per horse-power per hour—5d. or 10 cents. The motive power required for the purposes of the scientific commission is to be supplied free. The exhibition is to be open to the public twice daily, during the day and in the evening. The hours of admission will be fixed and published in due course. Exhibitors are to be entitled to free passes for themselves, their representatives, and for the requisite number of assistants and workmen. The general commission will provide that a strict watch is kept over the exhibits, and that proper order is maintained. The commission, however, does not hold itself responsible for any damage that may happen to exhibits through their or fire. The exhibitors are at liberty to insure their exhibits at their own expense. Exhibitors must provide that in the installation and working of their exhibits every danger to the public and to the buildings is avoided, and they must conform in this respect to the special arrangements of the general commission. The exhibits must be accessible to the free inspection of the public every day during the regular hours of admission, during the whole time of the exhibition. No exhibit is to be withdrawn before the close of the exhibition without the special permission of the general commission. Exhibitors must keep the space occupied by their exhibits in their own exhibits. Exhibits not to be sold by the exhibitor, manufacturer, and with his consent they may also bear the name of the firm which is authorised to sell them. Every exhibit must be clearly marked with the name of the exhibitor, the place of his abode, and the number of the exhibit. Price-lists, drawings, photographs, or other-wise, are to be given out by exhibitors only to visitors and buyers of the general commission. The sale and removal of exhibits may take place with the consent of the general commission; every object, however, which has been once sold is not allowed to be displaced. The receipt of goods at the Rotunda is to commence on June 1 next, and by May 15 all exhibits must be entirely unpacked and set up. The general commission reserves the right to dispose of the space not occupied by the 15th of May. The general commission claims the right either to complete such installations as are not finished in time at the expense of the exhibitor, or to exclude him entirely. One month after the close of the exhibition the exhibitors will receive back their goods removed their exhibits. After the lapse of this time all exhibits not removed will be sold. That time will be removed and deposited in the exhibition building at the expense and risk of the exhibitor. In cases of small goods not being removed within six months after the close of the exhibition, they are to be sold and the proceeds paid in the same way as the net proceeds of the exhibition, which, we may here mention, are to be devoted, with the concurrence of the Imperial ministry of commerce, either to further the aims of the exhibition, or to the pursuit of important inventions in the field of electrical science.

The general commission has taken the necessary steps to enable exhibitors to enjoy the advantage of the patent law from the time of the entry of their goods to the exhibition grounds until exhibition, and to enable foreign exhibitors will also receive a from duty in case of the re-export of their goods before the end of the present year. The special conditions relative hereto will be published hereafter.

No prizes will be awarded by the jury. During the exhibition a technical and scientific commission will be organised in co-operation with the exhibitors in order to carry out electrical measurements and other scientific investigations, and with a view to testify results. A scientific and technical lectures to be given during the exhibition, and the conditions will also appear.

The catalogue to be published at the opening of the exhibition. In cases of dispute or complaint the ultimate decision will be reserved for the general commission.

Such are the rules and regulations of the commission, which will be amplified and added to in detail as the necessity may arise. We have only to add that applications for space must be in the hands of the managing committee of the International Electrical Exhibition, I. Wallnerhofgasse 10, Vienna, at the latest by March 1 next. Applications in Vienna, at or from abroad, by means from the managing committee of the Rotunda of Vienna and Commercial Councillor, and Austrian-Hungarian consuls.

The acceptance of exhibits rests with the general commission, and applicants are to be informed of the decision of the commission within two weeks after the receipt of the application. Exhibitors are to be informed of the final allotments of space by May 1 next. The honorary presidency is held Hans Wilczek, the president is Victor Freiherr von Ertingshausen, and the managing committee are Herr Carl Pfaff and Rudolf Ritter von Grimburg. In conclusion, we have only to wish this exhibition the full measure of success which there is every reason to believe it will enjoy. Those who visited the Universal Exhibition of 1873 will no doubt have carried with them pleasant recollections of the metropolis of Austria. Since that time Vienna has made considerable material progress by the completion of many of its public buildings, by which its appearance and the interest incidental to its improvements have both been enhanced.

THE QUADRANT FLUE-TUBE BOILER.

We have recently had brought under our notice a form of multitubular boiler which possesses several novel features in construction and appears to be a very efficient steam generator. This is the quadrant flue-tube boiler designed and manufactured by Messrs. Beesley & Sons, of the Falcon Steel Tube Works, Barrow-in-Furness, and which we illustrate at page 46, of our present issue. In our engravings, fig. 1, represents a front elevation, and fig. 2, a vertical section on the line C D, of fig. 3, which is a horizontal section on the line C D, in fig. 2. These boilers are made in all sizes, having from 50 to 600 square feet of heating surface. The boiler we illustrate is 7 feet high over all, a feet in diameter, has 176 square feet of heating surface, and 3 square feet of grate surface. It is tested up to 100 lb. pressure, and run to a working pressure of 80 lb. The shell is made of 9-inch steel, the crown of 5-inch steel, and the tube plate 1 inch steel, the fire-box sides and smoke-box being of 7-inch steel. The tubes are of No. 12 gauge Siemens steel, 2 inches in external diameter. Messrs. Beesley have one of these boilers working which is 10 feet 6 inches high over all and 6 feet diameter, the fire-box being 4 feet diameter at the bottom and 3 feet external diameter, the total heating surface of the 220 square feet and the grate surface 20 square feet. This boiler is expected to be working very satisfactorily at 75 lb. pressure, having been tested up to 150 lb. by hydraulic pressure. It will be seen that these boilers are suitable for a variety of positions, and are well adapted for use owing to their lightness. They are simple, compact, and strong, owing to their cost and maintenance in working, having no awkwardly sloped plates to clean, no cramped or clumsy plates or brick linings. They possess increased heating surface in the quadrant tubes over straight tubes in the same space, and although there is no undue strain on the tube plates, they afford sufficient resistance to act as stays in boilers of small diameter. In boilers of larger diameter Messrs. Beesley have a simple but efficient plan of staying the tube plates, by means of screwed stays with nuts and tubes, so they all radiate from one centre, therefore are the shorter the larger the diameter of the boiler, and the more the check. Any single tube can be taken out and replaced; and every tube is easy to clean with an ordinary tube brush fitted to a spring steel rod. Then there is the increased effectiveness of the heating surface in the quadrant tubes, the flame being gradually checked all the length of each tube, its energy being spent before it reaches the end, which is far superior to a straight tube fixed vertically or horizontally. Messrs. Beesley have found that all through, no steam joint is required to create one, and the tubes will never require cleaning so often as horizontal ones. The boilers are free to expand and contract, and have been tested to 50 lb. beyond the steam ratio. In all respects then, these boilers appear to be well calculated to meet many of the requirements of steam users.

Occasional Notes.

STEAMERS WITH STRAIGHT STEMS.

A CORRESPONDENT in one of the daily journals, referring to the sinking of the Inman liner *City of Brussels* in the fog, which being going into her by the *Richard Hall*, asks what the advantages are of the straight stem as compared with the ships that it should be almost universally adopted when and vessels in such great demand in the case of low on collisions. We understand that during the last few years, of our large merchant steamer being sunk through collision with another, the vessel causing the disaster has been one with a straight stem. The question raised by this correspondent is undoubtedly one of importance to the shipowner, and appeals generally to all who entrust their lives for the time being to the steam ocean-transit companies. The distinction is that the straight stem colliding with force against the sides of another vessel cuts the unfortunate craft down forward, even underneath, the water line, thus rendering her doomed to sink, in many cases, raked backwards as regards her fore and fifteen inches, in relation to the keel, thus giving to this feature of the vessel much

ELECTRICAL APPARATUS AT THE MANCHESTER EXHIBITION.

The members of "The Junk Club," a new scientific association recently started at Cambridge, held a meeting last week at the Manchester Electrical Exhibition, when Mr. Hays read a paper on the electric lighting of the exhibition, and also gave a rough outline of the principles of the dynamo as illustrated at present in a few typical machines of the class, the storage of currents, and the methods of distribution and illumination. The dynamo machines, he said, might be broadly divided into three types, the series machine, the magnet machine, and the shunt. The strength of an electric current is affected, among many other things, upon the number of wire constituting the coil. In a series machine, the wires used in a short length, a thick wire and few turns. In a shunt machine, on the contrary, the current being weak, a thin wire and a large number of turns were used. Each machine had its advantages, and each was applicable to special purposes was not entirely determined. There were, however, two broad systems of lighting, the arc and the incandescent. For arc lighting the shunt machine was the most economical to arrange the lamps in series, because if they were done separately the external resistance was considerable, whilst if they were arranged in multiple arc the external resistance was very small. For arc lighting, therefore, series machines were used in practice. For incandescent lighting it would be impossible to put the lamps in series, because the failure of each lamp, being a complete break in the circuit, the magnetic force would be required to be so great that the strength of current would be so enormous as to anyone touching a wire, and be fatal. For this reason incandescent lamps were therefore arranged in parallel circuit as being safer for the latter purpose. For arc lighting, a preference existed for currents for these lamps, but if a continuous current, which was preferred, were used, a steam engine should be employed, as in this manner even a single lamp could be kept going. This was not the case with the alternate current, because the resistance of one or of a few lamps would be so high as to practically stop the strength of current used, although the field coils to excite a sufficiently intense force. For light of small power the system of series lighting was the most available for domestic purposes. In the application of electricity for illuminating purposes we were at present very much behind the current could only be distributed economically at a high difference of potential, or, as it was more called, pressure; but in our houses such a current would be dangerous, and quite inadmissible. Many inventors had promised many inventions. Mr. Edison had not got so far as to produce a lamp, but he had published their cost; but as to see Mr. Edison had a few days since taken out a patent for one of these that he proposed to use beginning to think like other people. He proposed a system of series lighting for a few lamps in the current in the future, a local system of distribution would be established. He was not sanguine that such a system of service in that streets was laid at 200 lb. pressure. It was certain that the pressure in the mains would be reduced to a safe point at the houses. Of course there must be a battery for every house, but it would be comparatively cheap, the only way that for every 200 lb. pressure of current there should be one square inch of surface in the conductor. Of course there were serious heating the wires. If an electric light circuit were taken either purposely as at a switch, or not out by the making of a lamp or by accidental severance of wire, an there would be formed capable of doing some mischief. He might be prevented by rain or some extent, for example, by using safety switches or cut-outs, and by employing care in the erection of the lines. For this work it had acquired a considerable number of men should be employed. Circumstances might, however, very easily occur as, for example, from short-circuiting or accidental joining over of the lead and return wire, or from the sudden failing of a considerable number of lamps, when the amount of current would be too great for the safety or the lamps, if not for the conductors. In most this safety under the heat of the increased current. These testing quickly effected before any accident could occur, and so broke the circuit that there was very much danger with the system. Having entered into a description of the Siemens and Edison lights shown in the exhibition, Mr. Hays called attention to several subsidiary machines in connection with the electric light, including an electric exploder, alarm, and to noises; a signal for a railway, by which an electric shock by any one in the galleries of the exhibition, which at present was not so applicable to railways by means of which a telephone could be stamped at once from any part of the works. A conclusion, Mr. Hays briefly touched upon the subject of electric motors. A dynamo-electric machine, either from a battery or from another dynamo, would revolve which it might be converted. Of course they might easily understand that a little rearrangement of the light would be required to give them the necessary amount of power, when driven by steam. It was, however, only when life exhibited two types of motors, the Siemens and the Hesketers, which were employed driving appliances in the exhibition, one in connection with the electric light, the storage batteries of the Electrical Power Storage Company. A vote of thanks to the paper was passed to Mr. Hays for his paper, and the members afterwards made an inspection of

Engineering, Dec. 2, 1878.

PORTABLE ELECTRIC LIGHT PLANT.

In page 646 we publish an engraving of an installation that formed part of the exhibit of M.M. Sautter and Lemonnier, Avenue du Suffren, Paris, at the recent Electrical Exhibition at Paris. It consists of a portable engine fitted with a Gramme generator and regulator and a Jacquin projector, and a length of conductor placed on a reel. The Gramme machine is driven direct by a Heathcoat belt from the engine. This installation illustrates a type recently adopted by the French Government for military services, and is especially intended for use in fortifications and other defences. We shall on a future occasion refer to this arrangement when we come to speak of M.M. Sautter and Lemonnier's admirable exhibit at Paris.

Germania exercise painstaking fore-thought in their work. Nothing is more likely to cause annoyance than complicating a piece of machinery with unnecessary parts. Simplicity of design and construction should be the aim of every engineer.

Boston, with a capital of $1,000,000. Cost of plant: Sixteen steam dynamos (two in reserve), capacity, 1,200 lights each, $166,800; boilers, $62,000; iron structure and foundations for same and for steam dynamos, $30,000; appliances, machinery and miscellaneous items being up the cost of the central station, exclusive of real estate or construction of elevations of building to $329,800. Underground street conductors for the proposed district, $120,000; services, $65,000; meters, $15,000; total cost, $530,800. Operating expenses are figured as follows: Salaries and wages at central station, $33,250; do. in other departments, $9,000; total salaries and wages, $42,250. Coal under, oil, and other supplies, $48,000; total operating expenses, $111,250. Depreciation of steam dynamos at 5 per cent. is figured at $3,150; boilers and settings at 7 per cent., $2,100; other items bring up the depreciation account to $10,650. Rentals at $7,200, taxes at $5,334, insurance at $1,200, and conversion charges at $8,000, bringing up the total annual expenditure to $182,460.

The progress of electric lighting is well illustrated by the electrical machinery now in use on board of the fast ocean steamer, Arizona, plying between New York and Liverpool. Our particulars are from *Engineering*. The Arizona is fitted with two of Siemens compound shunt wound dynamos, each capable of maintaining 300 high-resistance Swan lamps, driven by a pair of Shanks' "Celebrated" engines, with cylinders 9½x15 inches. Each dynamo is fixed upon an independent base plate, sliding upon guide rails in a foundation plate, which also takes the base that takes the strain of the driving rope is lengthened into a long slide, and the two machines are slightly displaced laterally, so that their faces interlock. By means of screws both dynamos may be moved backward to tighten the belts. There are ten grooves in each fly-wheel, but there is only one rope to each machine, and consequently but one belt. This necessitates the use of a guide pulley to lead the rope from the last groove of driving pulley. The axis of one machine is elongated, and is provided with a pulley for driving a tachometer mounted upon the top of the frame. The commutator brushes are set on a bracket, which can be rotated by a worm to bring the points of contact into the most favorable line, and this bracket, which is of large cross section, is jointed, so as not to impede the motion. By this machinery all parts of the great ship are brilliantly lighted with electric lamps. Looking back for only twelve months, immense advances are to be seen in this department of electric lighting. It is no longer a question with the Liverpool companies in what parts of the ship the light shall be used, for it is now applied everywhere, and both cabin passengers and ordinary seamen, in the forecastle, as the

ELECTRIC LIGHTING NOTES.

Despite the attention given to the members of the Liverpool Association of the United Kingdom meeting last month in Liverpool, the back cream of the Free Library was for the first time lighted by electric light. About 30 high-resistance Swan lamps were attached to existing fittings, the current was supplied from Faure-Sellon Volckmar storage batteries; this installation has been carried out by Messrs. Holmes and Vaudrey, Liverpool.

Engineering, Sept. 7, 1883.

THE CAGE ELECTRIC EXHIBITION.

The buildings of this interesting local exhibition in the old Normandy town are lighted by 261 Edison lamps fed by a K dynamo and a Z machine. M. Berjot exhibits his electric lamp in an improved form, and also a selection of Carré carbons, he being now associated with the house of Carré. The chief novelty of the Exhibition is, however, an electric clock of M. Ledoux, in which a heavy vane is added to the pendulum corrects by its mass the irregularities of the electro-magnetic action on the pendulum. There are also exhibited two electric clocks, which repeat the hour given by a standard clock, and thus distribute the time much in the same way as the pneumatic clocks of Paris.

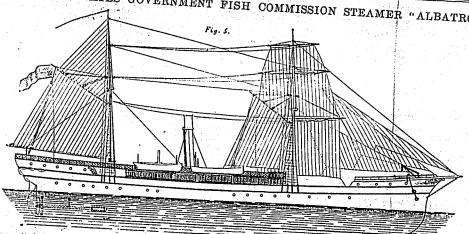
Engineering, Dec. 7, 1881.

THE JABLOCHKOFF ELECTRIC LIGHT.

On Wednesday evening a portion of the Hon Marshal Bazaine was illuminated with the Jablochkoff electric light, and the installation will probably be followed by an extension over the whole building. This system of lighting has had a long and successful career in a number of industrial establishments in this country, among which we may mention Messrs. Stoodleard and Co., who commenced its use three years ago with forty lights now to be increased to sixty; Messrs. Nicols and Son since 1879, and Mr. W. Whitelaw during the last twelve months. All of these gentlemen speak enthusiastically (after their prolonged experience) of the superiority of the arc light over gas, and it is an important fact that after three years' work, in as good a condition as when the machines were started. The Société Générale d'Electricité have lighted the Thames Embankment since the 16th of December, 1878, and during that time there has been no suspension of the light through any failure of the system, the only periods when it was not used being during other occasions invoked from the Board of Works.

THE UNITED STATES GOVERNMENT FISH COMMISSION STEAMER "ALBATROSS."

Fig. 1.



governors are attached to the main engines. An Edison dynamo and engine are used for electric lighting. Heat is provided by steam radiators in all inhabited quarters of the vessel. Ventilation is secured by means of conduits leading to all parts of the ship through which fresh air is drawn by the exhaust fan above mentioned, placed on a platform in the fire-room, and arranged to discharge downward in the direction of the furnaces.

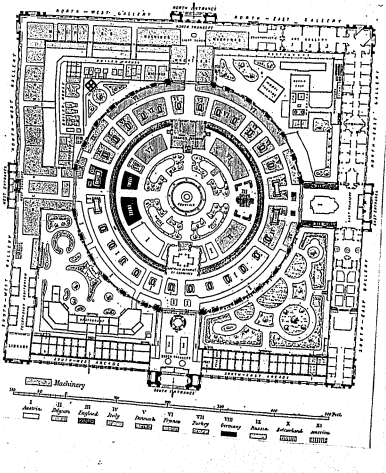
Light is supplied by 1208 candle 31 lamps of the Edison incandescent system and a 2 dynamo driven by Armington and Sims' high-speed engine. These lamps are distributed in all parts of the ship including holds and store-rooms; there are also twelve lamps outside for lighting the deck. In the laboratories the lamps are especially numerous and are pronounced to be quite sufficient for any possible needs. As are lamp of great power, designed by Dr. O. A. Mower, to work in circuit with the Edison incandescent system, serves for illuminating the surrounding surface of the sea. A powerful submarine lamp is also provided, which can be lowered to any depth not exceeding 1000 ft., to be used in deep-sea exploration.

Two steamboats are provided for the purpose of carrying on the work of scientific research. They are fitted with Herreshoff boilers. Other boats of special types are also carried.

A model of the Albatross is shown in the United States Court at the Fisheries Exhibition, together with models and full-sized examples of the scientific apparatus and gear necessary for the work the vessel is designed to accomplish. Amongst these appliances the following may be briefly mentioned, viz.: The Sigsbee deep-sea sounding machine, sounding reels, water cups, and gravitating trap for collecting specimens at the bottom; a dredge for which it is built by D. Halleny, Washington, D. C.; Tanner's sounding machine for depths under 1000 fathoms and for navigational purposes. The dredging boom 36 ft. in length with 10 in. in diameter, the heel of which is pivotted to the forward part of the foremast 7 ft. 2 in. above the deck; the dredging block at the boom end, the chain and register at the heel of the boom for indicating the length of dredge reposed, and thence combined at the foremast head arranged to prevent jerking strains on the rope (the commutator used is of the form recommended by Commander Sigsbee, U. S. Navy). The Negretti and Zambra deep-sea thermometers with the Buffa and Tanner improved cases. A Chester rake dredge, a beam trawl, a deep-sea trawl, a Chester towing net, together with tangles, table nets, trawl lines, and other minor apparatuses, complete the scientific outfit of the vessel.

PLAN OF THE VIENNA ELECTRICAL EXHIBITION.

(For Description, see opposite Page).



THE VIENNA ELECTRICAL EXHIBITION.—No. I.

THE Exhibition of Electricity which has now been opened for some weeks in Vienna, is an interesting illustration of the activities in a new more forward, and developed without any Government assistance, except that the great Rotunda which formed the conspicuous feature of the International Exhibition of 1873, was placed at the disposal of the Executive Committee. The Munich Electrical Exhibition held a year ago, proved the value and the completion of the undertaking at Vienna, and the opening ceremony of the latter, after having been postponed several times, and at last fixed for the 1st of August, did not take place till the 16th. After the time had elapsed for unpacking and displaying the last exhibits, and in getting the various series into working order, the Exhibition, completed and finished on the 1st inst.

The general catalogue gives the names of 372 exhibitors, several of which are repeated. If we divide them by nationalities the numbers are as follow: Austria, 247; England, 29; Germany, 31; United States, 6; Belgium, 18; Denmark, 9; France, 124; Italy, 19; Russia, 29; Sweden, 12; Switzerland, 10; Turkey, 1. The plan we publish on the opposite page shows how the exhibits of nations have been distributed in the Rotunda and its annexes. Austria and France occupy each one third of its area. England, as will be seen, is represented by an insignificant number of exhibitors. This indifference is to be regretted, but finds its explanation partly in the fact that so many electrical exhibitions have been held since 1881, partly to the season of depression that has naturally followed the exaggerated and inflated period of the electric light palaces, dazzling meals, and partly because no large and complete an exhibition of electric lighting is now occupying the attention of various companies and inventors at South Kensington. The arrangement adopted in the catalogue does not take into account the nationalities of the exhibitors. The circular form of the building lent itself to a methodic classification very advantageous for visitors. This classification follows a regular order starting from the main South Pavilion. The numbers run consecutively from this point towards the right, follow the circumference of the Rotunda and are continued further to the point of starting, where the last number is opposite the first. This arrangement, which is very simple and convenient for visitors, would complicate our description if we followed it, and it will be preferable to take successively the great divisions of electrical industry, in such a way as to collect and compare in each article the apparatus of different exhibitors having similar objects.

Before describing, on this system, the contents of the Exhibition in detail, we may throw a general glance over the building as a whole. Access to the Exhibition from some distance may be obtained by a small electric railway laid down by Messrs. Siemens and Halske, of Berlin. This tramway, which we shall describe hereafter, has one terminus at the northern entrance. The road to the south door will be lighted at both sides by rows of incandescence lamps, but until a few days since only a part of these were in place. Both entrances are lighted outside by lamps of various systems. In front of the south door were two 24-h. lamps, on wrought-iron columns, each carrying at the top a group of six arc lamps, covered and protected by a large sheet-iron hood. The violent storm of the night of the 2nd inst. threw them to the ground, breaking them into a thousand pieces. The next day their places were taken by a number of poles, not so high, but stronger, carrying each two arc lamps, which give a finer and more evenly distributed light. At the top of the interior of the Rotunda is a series of arc lamps that scintillate like a circle of diamonds. Lastly, two projectors placed symmetrically on each side of the building throw in full arc lamps. Entering by the southern door, which is the chief portal, we find ourselves in the Austrian Section. We first pass through a transept, the middle of which is occupied by the Imperial pavilion, a small structure simply decorated. We then pass the pavilion of Austrian telegraphy, and arrive in the centre of the Rotunda. This is occupied by a great fountain with nothing however of a monumental character, having in the centre two cement mushrooms covered with zinc, and supported below each of them are Archimedes cochlea in globes; the effect of these behind the continuous sheets of water flowing over the central mushrooms would be doubtless very beautiful, if it retain itself a definition. The first circular zone around this centre is devoted to a restaurant and military bands. It is from this point the visitor looking upwards will best see the lantern of the great dome with its crown of arc lamps, and lower down at the level of the springing of the roof a second and larger circle of similar lights.

Around the central platform are ranged a number of pavilions. They are as follows: 1. Opposite the Austrian telegraph building, and symmetrical with it, is the fine exhibition of the French Department of Telegraphs. 2. Opposite the eastern entrance is the building of the English General Post Office. 3 and 3, near the western entrance, that of the Turkish Telegraphs. 4. Then come the exhibits of railway signals of the Northern of France Railway, the Paris, Lyons, and Mediterranean, &c. Beyond these pavilions, and ascending several steps, we come to the great circular gallery where the chief of the exhibits are arranged. Between the outer walls which enclose a square, and the circle of the Rotunda, are four areas also devoted to the Exhibition. The most interesting of these is the north-western pavilion, in which are placed the motors and the electric generators. We shall devote considerable space to this portion. The north-eastern corner contains a restaurant; in its external gallery is an exhibition of pictures, and a number of apartments richly decorated and furnished to show the effects of the electric light on fabrics, colours, furniture, &c. Leaving this gallery we traverse the eastern transept, the middle of which is occupied by a Turkish pavilion, and arrive at the theatre, where ballets are given every day. The scenic effects and the general illumination are of course produced by the electric light. This section contains also a restaurant; the south-east gallery which limits it, is occupied by a part of the offices, &c. of the Exhibition. Lastly, the south-west section contains a gallery for public telegraphy, a pavilion, a garden restaurant, and the other offices.

Following as rapidly upon the exhibitions of the last two years, this one at Vienna cannot be expected to offer any unexpected novelties. There are collected there machines and apparatus very similar to those shown in Paris and in Munich. But there are besides those well-known types, varied and ingenious arrangements, and characteristic developments, to which we shall return. As regards its official organisation and its general aspect, we may say without hesitation that the Exhibition is an absolute success, and the exhibitors could not expect to find facilities and accommodation in a more spacious and commodious building, the only fault of which is, that it is somewhat removed from the centre of the town. The arrangement adopted for classification is very convenient, and the circular form of the building lends itself to easy examination and comparison of objects, shortens the distances to be traversed, and simplifies research. It is also perfectly adapted for illumination, and attracts thou-

bands of people nightly. The height of the lamps and their arrangement in three concentric circles undermines the light and softens it, while the shape of the dome, which, as will be remembered, is that of a truncated cone, reflects the light well and destroys dark shadows. The great circular gallery, the machinery-room, and the annexes, are also abundantly furnished with light. This part of the Exhibition, which forms the greatest attraction to the public, is daily more appreciated, as is shown by the ever-increasing number of visitors who are not unfrequently refused admission. Thus on Sunday the 9th September, more than 10,000 persons were turned from the doors.

Already a series of conferences has been announced, and several thousands of workmen have availed themselves of the special arrangements made for them, including gratuitous admission. The Technical Committee has commenced its researches on the various apparatus shown. The outcome of the Exhibition is naturally the most interesting for engineers, and it is deeply to be regretted that the publication of the result of work of this kind is usually so slow. It is only now, after a year's delay, that the reports of experiments at Munich are being made known. If the executive at Vienna can reduce this delay, which so greatly detracts from the value of the work done, they will earn the gratitude of all who wish to obtain a solid advantage from the Exhibition.

[DEC. 5, 1882.

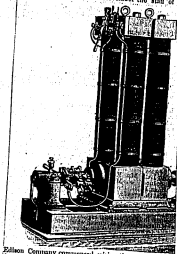
ENGINEERING.

THE ELECTRIC LIGHTING OF CHELSEA.

THE Vestry of Chelsea has received notice of the intention of seven electric lighting companies to apply to the Board of Trade for provisional orders under the Electric Lighting Act of 1882. The applicants are the Metropolitan Brush Company, the Edison Company, the Swan Company, the Edison-Jost Company, the Gilchrist Company, the West Middlesex Company, the Crompton, the Hermuti, Thomson, and Ince (Limited). In addition to these, the Metropolitan Brush and the Jablochkoff Company have asked the consent of the vestry to the granting of licenses. As the terms of the Act oblige local authorities to come to an immediate decision as to whether they will undertake the work themselves, or allow it to be carried out by private enterprise, Mr. George H. Stayton, the surveyor to the vestry, was instructed to draw up a report for the assistance of the members. In this report, which is published, after recalling the chief provisions of the Act, and pointing out the difficulties to be encountered, Mr. Stayton gives a list of twenty questions that he addressed to the companies, and also to Messrs. Siemens Brothers, with the object of obtaining such information as would assist the vestry in deciding what course to adopt. The replies that were received did not answer the intended purpose, being, as a rule, too general to be of any service. Most of the companies propose to begin operations in the main thoroughfare, Sloane-street and King's-road, and gradually extend them as the light became popular. The Brush Company contemplates supplanting the present 1250 street lamps by 400 arc lights of 2000 nominal candle-power each, for which the fixed annual cost is put down at 10,000*l*. They would supply 5,000 8-lights of from 10 to 100 candle-power by other purposes, and would charge for current by measurement at the rate of 8*d*. per 1000 cubic feet. This is about equivalent in price to gas at 3*s*. per 1000 ft. The Edison Company furnished very little information, except that it would employ incandescence lamps only, and that although it was at present lighting the Holborn Viaduct at the price of gas, that contract could not be regarded as a precedent. The Jablochkoff Company mentioned 1*d*. per lamp per hour as the probable cost to the vestry itself. Private users would be charged a price for each candle that would include cost of current also, whilst incandescence lamps would be a matter of arrangement, taking gas as a basis. The Swan Company is prepared to take gas as the standard, and to supply an equal amount of light at the same price, stating that this will leave no margin of profit until improvements are made in the cost of production of the current. The Farmuti Company is anxious that the vestry should be the undertaker, but is willing to equip and work the station for some years on a payment, based on the number of lights, that will furnish a dividend of 10 per cent. on the capital. This, it is thought for street lighting, would be about twice the cost of gas, with three times the illumination. The Thomson-Jost Company proposes to use three classes of lamps—arc, semi-incandescence, and incandescence—but do not give an estimate of the cost of the light. Messrs. Siemens Brothers and Co., who were not among those who applied to the vestry, and who state they do not wish to undertake contracts of this kind, refer to *Dr.* Siemens' late address as an answer to questions relating to cost. Thus, it will be seen that Mr. Stayton obtained little information in answer to his question, except that no one knows exactly what electric light will cost, and that no firm only is willing to contract to supply it at the price of gas. Under these circumstances, Mr. Stayton no doubt acted wisely in advising the vestry not to become the undertakers, and to formally oppose all applications, in order that clauses might be inserted in the contracts to protect the interests of the ratepayers as far as possible.

THE ELECTRIC LIGHT ON THE S.S. "TARAWERA."

THE Edison Electric Light Company, Limited, recently a contract recently for lighting two ships belonging the Union Steamship Company of New Zealand, viz. Tarawera and the Waikera. The Tarawera was built by Messrs. Denny Brothers, at their yards at Dumbarton, and on the 21st of November the staff of the



Edison Company commenced wiring the vessel. The dynamos and engines were placed in a small room, 12 ft. by 11 ft. and 7 ft. high, opening into the engine room, the floor being on a level with the gallery running round the wing of the cylinders of the main engines. The wiring of the vessel is done in the most careful manner, nothing but the most highly insulated wire, protected by an india-rubber covering, and over that a tenacious, which we have already illustrated and described in this journal, and which has been long in successful use.

The engine is fitted with a handy arrangement of steam valves, whereby, if required, steam can be admitted to the low-pressure cylinder for starting the engine with the cranks in any position, the possibility of the arrangement consisting in the fact that the steam admitted has all other steam has to pass through the throttle valve. This simple arrangement removes a difficulty which has been experienced with some engines, as no engine so fitted can never overrun, whatever may be the position the starting valves are left in.

The governor, of which the illustration sufficiently shows the design, is of the high-speed type, running 200 revolutions per minute, and efficiently controls the engine. The boiler is of large size, as is also the fire-box, so that wood, sawdust, or refuse can be burnt. The boiler is machine riveted, and rises can be burnt. with a damper at both front and back, and the fore pedestal is made to serve the purpose of a water-tank. In some cases provision is made for filling each crank-pin by a fixed lubricator, having a sliding cock and wick, which is touched at each revolution by a wiper on the connecting-rod collar, thus only once taking off a drop of oil. This plan, which has been found to in marine practice, is convenient when the lamps have to make long runs without stopping. The engine illustrated is of substantial proportions, and all working parts are made strictly to gauge, so as to facilitate renewals.

THE HARLEM RIVER BRIDGE.

(Concluded from page 406.)

We this week complete our illustrations of the bridge over the Harlem River at Eighth Avenue, New York, with a two-page plate showing the turning gear for the central swing span. At 2 is a plan of the arrangement, and Figs. 31 and 32 are axial sections at right angles. Upon a cast-iron base ring is fixed a toothed roller path, and around the edge is fixed the toothed circle shown in Figs. 30, 31. The rollers are connected to a ring placed around the centre socket in which the centre rests, by means of rods converging radially. The upper roller path is attached to the ring girder which carries the superstructure of the bridge. The drawings show clearly the arrangement of the engine, boiler, water tanks, &c., as well as the mode of transmitting the power required for turning

GINE.
RS, BASINGSTOKE.

ELECTRIC LIGHTING NOTES.

Hitherto the electric light installations in Scotland have shown that the Brush system is the most popular north of the Tweed, whatever it may be elsewhere. It is certainly the one that has up to the present been most extensively selected in the shipbuilding yards and engineering works of the Clyde and the Glasgow district, and launched are some of the installations. Three out of the last six installations fitted by Mr. Richard Miller, of Glasgow, who was agent for the Brush system in Scotland prior to the advent of the Scottish Brush Electric Light and Power Company, Messrs. Russell and George Thomson, the firm of engineers and shipbuilders at Cardonald, have certainly got the most extensive electric light installation in hand. It consists of 37 2000-candle lamps, 17 of which are driven by one dynamo, and the remaining 20 by another. The same firm are also fitting with the arrangements for carrying out an installation of from 20 or so of Swan's incandescence lamps, distributed through the offices, model room, &c., and worked by a Gramme dynamo, formerly used with some dozen arc lamps. Next in order, mention should be made of Messrs. Mirrlees, Watson, and Co., the enclosed engine and mill engineers, Glasgow. They have two Brush installations. Some of the lamps were in use in the firm's extensive foundry, but we understand that they have been withdrawn from that establishment, there being greater need for them in the engine works. We are informed that these, Messrs. Mirrlees, Watson, and Co. are also going on with an installation of at least 70 5000-candle lamps. At the marine engineers' shipbuilding works of Messrs. Caird and Co., Greenock, there are 16 Brush lights in use. Messrs. D. Napier and Son have just completed a Brush light installation, giving six lamps in each; and the firm are said to be making arrangements to place the electric lighting engineer, At the Newton Works of the Steel Company of Scotland there is an installation of 17 Brush lights in use, all driven from one machine. In this case, it is said, there is no mention that the works are considered as beyond the range of the present gas supply—namely, beyond Cambuslang. The Hopetoun Works of the same company, which are inside the burgh of Glasgow, are lighted with gas. There are six Brush lights in use at various points of the works of the James Watt Dock, Greenock, and in this case progress towards completion. The first shop in Scotland to be lighted with electricity is a very extensive retail grocery establishment in Glasgow, that of Messrs. Cooper and Co. There are a couple of 2000-candle lights worked by a small Brush dynamo, which is itself driven by an Otto gas engine.

At the last monthly meeting of the Town Council of Renfrew it was reported that the Magistrates' Committee had had under consideration the question of supplying for payment under Mr. Crompton's plan the numerous lights in the town-hall's dark to see that not to do so, and to oppose any private company applying for such powers, as the ground would be protected in the Report for the Board of Trade to grant a further order to any company for that purpose. The action of the committee was approved of by the Council.

One of the most interesting electric light installations yet attempted in Scotland was completed and opened for public view on the evening of Thursday, the 30th ultimo, in the extensive drapery, millinery, and fancy goods warehouses of Messrs. Walter Wilson and Co., Sauchiehall-street, Glasgow. No fewer than three hundred lights are employed in this installation, and in each case a Crompton-Hopkinson dynamo is used for generating the current. In two circuit there are eight lamps, and in the other three Crompton arc lamps are used. Sixty Swan incandescence lamps are in the premises and other out-buildings throughout the shop. Owing to the lowness of the ceilings throughout the premises and other out-buildings throughout the shop, the arc lamps have not yet been put up, but will be fitted to the roof of the building forthwith. The installation has been carried out by the Crompton Electric Light Company, Limited, of Glasgow, and the contract is to last for the next three years. The electric engine and the dynamos are kept on their own premises, and provide their own property. In fact, in a word, the firm simply contract to supply the light, and to keep it in repair. The whole of the new light will be cheaper than the old one. Certain parts of the warehouse are still lighted with gas, and are likely to remain so. This is, we believe, the first instance of a soft goods warehouse in Scotland using the electric light.

A Bill is being promoted in Parliament by the Harbour Commissioners of Berwick, which, along with other things, asks for powers on the part of the Commissioners to provide for the lighting of their harbour, dock, and other works by electricity or otherwise, and for that purpose to do any, or all of the things that are being asked for by municipal authorities in provisional orders under the Electric Lighting Act, 1882. They also wish to be authorised if necessary, to enter into agreements with the Berwick Town Trustees for lighting with electricity the harbour and dock works of the town and burgh itself.

On board the steamer Tarawera, the latest vessel built by Messrs. William Denny and Brothers, Dumbarton, for the Union Steamship Company of New Zealand, a most successful display of the electric light by means of the Edison incandescence lamps, was given last Saturday afternoon and evening, whilst the vessel was lying in the Albert Harbour, Greenock. For a period of three hours there was a private view, at which there were present by invitation a very large number of guests representing the shipowning, shipbuilding, engineering, gas manufacturing, and allied interests of Glasgow, Greenock, and other towns on the Clyde and throughout the West of Scotland; and subsequently for another period of three hours the exhibition was open to the public on payment of 6d. per head, the proceeds being devoted to the Greenock Infirmary. This is the first public exhibition of the Edison lamps in Scotland, and the success attending it will doubtless have excellent results. On another page of the present issue we publish a more detailed and illustrated notice of this installation. The arrangements for the exhibition were made by Mr. Charles T. Great Hope-street, Glasgow, agent for the Edison Company; and the practical arrangements for the lighting of the ship were carried out under the superintendence of Mr. Alexander Macdonald, the electrician for the company in Scotland.

At the last ordinary meeting of the Philosophical Society of Glasgow, Sir William Thomson read a long and interesting verbal communication on "Anticontinuities and Discrete Measurements of Size, No. 2, Cloudy Air, Electric and other Artificial Lights." He experimented on the diffraction spectra used in illustration of the remarks made by the distinguished professor. We hope to return to the subject in a future issue.

The contract for lighting the Courts of Justice by electricity was given to the Swan Company some time ago, but there can be before the opening day it was decided that the hall should be ready for the inaugural ceremony. As it is, the original scheme of lighting is being carried out throughout with Swan incandescence lamps with the available lines, and Crompton's are lamps of 2000 candle power each were placed in the great hall for the opening day. The fittings in the cloisters and approaches to the great hall on the ground floor, in the east and west spire staircases, in the corridor and in the corridor, and in some of the courts were so far advanced that the lamps were able to be supplied in time, a 60 horse power Crompton engine has been fixed outside the main building. The whole installation is an example of extreme rapidity of execution. Within fifteen days a huge mound of rubbish was levelled, foundations laid, and the engine fixed. A line of 3in. steel shafting, with all its bearings, couplings, and pulleys was manufactured and fixed in five days, a dynamo erected, and a line of wire laid over the whole of the inside the building four miles of Swan lamps have been fixed, and 200 sets of fittings for the lamps and holding gear have also been made and fixed.

The "duplex" incandescent light has been installed in the Wemyss Chapel of St. Amiel, Dunvastle. This is the largest installation of the kind yet made in the county. There are now twenty lamps of 20-candle power each, and these are fed by the current from a Siemens dynamo of one of the type running at 1200 revolutions per minute. The machine lamp, devised by Dr. Siemens, has two sections so connected that the current can be sent through one or through both either in multiple arc or in series. This forcibly gives it a practical advantage over the ordinary single filament lamp in that it yields two different intensities of illumination at will by turning a cock in the stands of the lamps, and this without changing the quality of the light, as happens when the current is reduced in single filament lamps. The "duplex" lamp would therefore seem to be specially adapted for churches and places of worship, where they are lowered during the services. We may add that Canterbury Cathedral is to be lighted by these lamps by the South-Eastern Brush Electric Light Company.

Engineering, Dec. 1st 1882.

ELECTRIC LIGHTING NOTES.

The Swan United Electric Light Company have published notices of various applications they propose to make to the Board of Trade, under the Electric Lighting Act of 1882, for powers to establish lighting installations in different parts of London. One of these, the so-called Victoria District, includes portions of the parishes of St. Margaret's, Westminster; St. John the Evangelist, Westminster; St. George, Hanover-square; St. Martin-le-Grand; and St. Anne, Soho; St. Paul, Covent Garden; St. Mary-le-Strand; St. Clement Danes; St. Andrew, Holborn; Trinity Church, Marylebone; St. Pancras; and other Artificial Lights." No. 2 of the Strand, the Liberty of the Rolls, Lincoln's Inn, Staple Inn, and the Inner and Middle Temples. A topographical map of the district to be lighted is part of the application. Another district, known as No. 3, includes St. Margaret's, Westminster; and St. Luke, Chelsea, parts of the two last-named parishes being also included in the first notice.

The vestry of the parish of St. Pancras give notice that they will apply to the Board to establish electric lighting within their parish, as well as to erect the necessary buildings, and to place the requisite mains, lamps, meters, conductors, &c., for the production, distribution, and utilisation of the current.

The Pilsen Joel General Electric Light Company proposes to deal with the Holborn and St. Giles districts, including parts of High Holborn, New Oxford-street, Tottenham Court-road, Little and Great Queen-street, Dudley-court, Field Court, Theobalds, and Wakeley-street, Clerkenwell, Chalk Farm-road, High-street, Camden Town, and part of Hampstead-road.

The South-Eastern (Brush) Electric Light and Power Company will apply for the necessary powers for producing, storing, and distributing electricity in Fulham, Hurgate, Canterbury, Maidstone, Richmond (Surrey), Croydon, Catchem, Gravesend, Rochester, and Chatham. The same company also will seek similar powers for Lowestoft, Aldeburgh, Great Yarmouth, Ipswich, Bury St. Edmunds, Cambridge, Luton, Bedford, and High Wycombe. The company, in fact, appears desirous to cover the whole of the districts in which they work.

Messrs. Fernsall, Thomson, and Ince, the proprietors of the Fernsall system of electric lighting, to which we refer on another page, are applying for compulsive powers in the metropolitan districts. One area they propose to supply includes the whole of the parish of Chelsea, except the district of Kensal New-town. The second applies to the parish of St. John, Hampstead, and besides a long list of streets comprises such parts of the following as lie within the parish: the North London, the London and North-Western, the Midland, the Metropolitan, and the Metropolitan and St. John's Wood Railways.

At a recent meeting of the Nottingham Municipal Council a resolution was passed to make applications direct to the Board of Trade for power to supply electricity for public and private purposes within the area of the borough, and a special committee was nominated to take charge of the work.

One of the first instances of the employment of the incandescent electric lamp for the lighting of a West End shop front is probably that of Mr. Smyth's at the corners of New Bond-street and Grafton-street. Since September last thirty-six Swan lamps fed by a Gramme machine have brilliantly illuminated the life-size photographs in the window. The work has been carried out by Messrs. Parsky and Son, of Berners-street, W., who have designed special fittings representing a Renaissance pilastered arm, flanked by vines, from the tendrils of which the little bulb lamps are made to depend. The cable is a complete departure from those in vogue for other installations, while the central feature of the arm has an appropriate reference to the photographic art.

After a good deal of coquetting and negotiation, continued over two or three months, between the British Electric Light and Power Company on the one hand, and certain members of the Queen Council of Stornoway and other persons discontented with the treatment which the gas concessionaires have meted out of the local gas company on the other, all symptoms of immediate or even an early electric illumination being started in that town is now at an end. The British Company seem to think that the "game is not worth the candle."

ENGINEERING, Dec. 1, 1882.

THE MUNICH ELECTRICAL EXHIBITION.—No. V.

RAILWAY working was represented at the Munich Exhibition of Electricity, by the Administration of Bavarian State Railways, by the Austrian State Railway Company, and by the French Northern Railway Company. This last-named exhibit, organised by M. S. Sartiaux, chief of the Telegraph Department of the railway, comprised a number of apparatus that had previously attracted great interest and attention at the Electrical Exhibition at Paris. In our present rapid review of the contents of an exhibition, closed several weeks ago, it would occupy too much time and space to give anything like a detailed description of this highly interesting collection; moreover, many of the apparatus are far from new, and have been already described either in this paper or in separate memoirs. We will, therefore, content ourself with little more than a list of the objects shown. These included (1) types of the electric semaphore of MM. Tesse, Lartigue, and Prudhommeau, employed for working the block system, which exists over the whole system of the Northern Railway, about 600 miles, and possessing 435 signal boxes. These semaphores are supplemented, in cases where they are out of sight of the station employés who have to be advised of the arrival of a train, by a repeater of the signals given by the semaphore. Such a repeater was also shown. (2) Sources of electricity for the bell signalling, and commutators for changing the direction of the current. The source of electricity employed by the Northern Company is a Siemens induction machine, constructed by M. Digney, and composed of a large coil, revolving between the poles of twelve bar magnets. The apparatus is a very simple one, and a half-turn of the driving handle is sufficient to release all the bells in connection with the system, and to enable the telegraphists to employ for occasionally signalling various running latterns any two stations, the commutator of M. Sartiaux is employed. This consists, when, in the form of a box, does not interrupt the circuit when it is closed, but breaks it as soon as the box is open, and contacts are so involved in the desired directions. (3) Level crossing alarms. These are employed to notify the guards of trains when they approach level crossings. They comprise an automatic pedal and whistle, an automatic mercury pedal, electric bells for single lines, and the semaphore repeater on lines worked by the block system. The first of these dates from 1859, and was designed by M. Lartigue and M. Tesse. The second is due to M. Lartigue, and is now being tried. It consists of a very light pedal fixed to the levels of the rail, and placed 2 kilometres from the level crossing to be protected. It carries a small ebonite key, containing mercury, and is connected to a spring which projects a little above the top of the rail. The flanges of the wheel depress this spring and slightly incline the mercury key, the displacement of which produces electrical contact between two platinum wires which put the bells and earth wires in communication, and the circuit in which a bell is placed is thus completed. The bell once started by the passage of the train, continues to ring until the signalman stops it. This is effected by a shoplike device that has been added to the bell mechanism. A small lever turning on a metal pin is in connection with the battery. When at rest the lever is held by a stud of insulating material fixed to the pallet of the hammer. When at the moment that the pedal is depressed by the train, the hammer is attracted towards the coils, the lever is released and falls on a metal stop which thus throws the bell into the circuit, and the ringing continues until the lever is replaced by hand. A slight pressure on the lever which projects beyond the box of the apparatus is sufficient to effect this. An electro-semaphore repeater for level crossings in use on the Northern Railway. The type of apparatus that was exhibited is placed between two semaphore stations and in the circuit of the lines connecting the apparatus of the two stations. When the employé moves the long arm of his semaphore to block his section and signals the train to the next section, the current which forms the small arm first traverses the repeating apparatus and throws up the arm of a small signal outside it. As long as this small signal remains visible, one of the bells (there are two, one for each line and each of different tone) notifies the employé at the level crossing that he must not lower the small signal until the train has passed. The repeating apparatus consists of a small iron box containing two Hughes electro-magnets, which hold each of the two small signals slightly inclined to the direction in which they fall. When by the passage of the current the effect of the magnets is reduced, the signals fall by their own weight outside the apparatus, and as soon as they have fallen to their full extent they make contact between two springs, to which are connected the two poles of a local battery and two bells.

(4) The electro-automatic whistle and electro-automatic actuator for the vacuum brake. As a rule all dangerous points and crossings are protected by visible signals, supplemented as far as possible by acoustic signals calling the attention of the employé. The apparatus for the latter purpose was exhibited by the Compagnie du Nord, is the electro-automatic whistle of MM. Lartigue, Forest, and Digney, and which is in use on 289 locomotives. The company having adopted the vacuum brake, MM. Debilecque and Hunsdorff have changed this apparatus into one for working the brake automatically. An example of this system was shown on a model locomotive and train. The mode of action is briefly as follows: In the centre of the track, at a fixed distance from the signal, is placed a "crocodile" made of a wooden sleeper, covered with an insulated leather, and connected by a wire to the positive pole of the battery working the bell for the disc signal. Upon this piece rubs a metallic brush fixed to the locomotive. This brush is connected with the wire of the coil of a Hughes electro-magnet. If the signal is open, the circuit is also open, and the passage of the brush on the fixed contact produces no effect. If on the contrary the disc and the circuit is completed, and the current through the electro-magnet and the starting apparatus releases the brake, the noise of which notifies the driver, who will then leave the brake on, or take it off according to circumstances. The fixed contact is about 6 ft. long, and the speed of the train of course for one-tenth of a second at the highest speeds, sufficient to start the brake. The automatic whistle in use before the adoption of the vacuum brake, differs from the foregoing only in that the starting apparatus is replaced by a steam whistle, the valve of which is operated by the rod projecting from the starting box. It continues to sound until the driver sets back the armature.

(5) Electro-automatic apparatus for protecting stations or junctions. The company exhibited the special apparatus now being tried at several places on their system, and which is intended to secure the same advantages as the automatic disc signals, without the danger of break-down to which the latter system is liable. The apparatus worked out by MM. Forest and Lartigue, on data afforded by M. Mantion, is based on the use of the electro-automatic whistle, and on the employment of fixed contacts. The ringing spy of the arrangements or mode of working the ordinary disc signals, the inventors have obtained the following results, by the addition of a special electric commutator placed near the lever of the disc, and by the addition of a second fixed contact to the foot of the signal. When an engine fitted with a metal brush passes before an open disc, the friction of this brush on the first contact actions. It then releases the electric apparatus placed near the lever of the disc and rings a special bell in the station, which notifies that a train has entered the section between the disc and the station, and that it must be protected. In the second place, by the act of releasing the apparatus, the first contact placed 200 metres in advance of the disc is automatically set in relation with the source of electricity, without which it would be necessary to turn the disc round to the stop. From this it results, that if a second train passes over the fixed contact either the automatic whistle or the Smith brake is put into action and the driver is notified that the train has passed a disc, and has not been protected by setting the disc to close the line. He will therefore stop the train as rapidly as possible. As soon as the disc has been restored to its normal position, the train apparatus also resumes the same condition as before the train passed.

(6) Electrical controlling apparatus for working points. Points are often placed at a considerable distance from the men controlling them, and are consequently removed beyond the range of his intelligible observation. In order that the man may know whether the points have followed the action of the lever, and if they have been completely thrown over, M. Lartigue designed a contact apparatus, subsequently somewhat modified by M. Sartiaux, and which was approved by a ministerial decision on the 17th of December, 1878. This apparatus in its general use on the Northern Railway, and is as well known that we consider it here only because it was included among the company's exhibits at Munich.

(7) Apparatus for controlling the releasing gear of Messrs. Stanley and Farmer. The Northern Railway Company has added to the latter apparatus a releasing gear a system of electrical control devised by M. Sartiaux. By means of this the man at the central station shall be able to ascertain whether the disc signals are in proper working order. Four models of these apparatus were shown.

(8) Electro-magnetic bells for lines only becoming occasionally independent of the telegraphs, as usually sent by telegraph, providing for the exchange of a certain number of momentary communications that can be made by imperfectly educated servants, and for whom the ordinary instruments are too complicated. The Northern Company, also showed several types of commutators applied to the electric control for the working of distance disc signals. These commutators are generally formed of a piece of cast iron, fixed to the upper part of the signal post, and carrying a lever, turning on a copper axis, and provided at one end by a contact spring. When the disc is brought against the stop, a finger placed on the back of the disc signal raises the lever and closes a circuit, the battery of which is placed at the foot of the signal, and starts the bell ringing. A small model of a train illustrated the Prudhommeau system of communication, used by the company since 1865 on all passenger trains. Among this interesting collection contained various telegraphic apparatus, Lockwoke's dials of Paines used by the company, electric water level indicators, on the Verdi and Lartigue systems, electric apparatus employed since 1875 for lighting the Chapelle stations, and considerable Siemens generators, and Serrin and Siemens' lamps, telephonic stations, &c.

Nature, p. 1877

NATURE

OUR Paris correspondent writes: We were present at the Alliance Electric Works to witness an experiment on the new candle-light, which we had seen in operation at the Physical Society, and which was recently described in NATURE. The Ruhmkorf machine was fed by a more powerful primary current given out by an Alliance electro-motor of three-eight centimetres long, and fully equal to eight gas-burners. At the same time three arc-called electric candles were in operation, each of them giving about forty gas-burners, and fully equal to five candle lights. Consequently not less than twenty-five lights could be fed at once in separate parts of the same building or at any distance. The light is admirable for its constancy and steadiness; the quantity of candle destroyed is quite insignificant—no more than 1 mm. per hour; the thickness of the candle plate or bar used is not more than 4 millimetres. The electric candles are formed, as is known, by two graphite bars separated by a candle bar. It was proved that the agitation of the candlestick produces no interruption of the current. Consequently a single Alliance-work machine can feed the three lights required by the regulations for steamers. The graphic pencils are consumed at the rate of eight centimetres per hour, which is a difficulty; but it is expected that any length required may be supplied by means of a proper clock-work. Experiments were tried on the same day at the Palais de l'Industrie for the purpose of illuminating the exhibition of pictures with electric light. The ordinary Gramme machines were set into operation. The light was found steady, but the effect was not quite favourable esthetically. It is expected that with the system of light division, an improvement may be effected. The experiments were made in order to test whether electric light may be utilised on the occasion of the forthcoming International Exhibition.

ENGINEERING.

ELECTRIC LIGHTING NOTES.

The Corporation of Bury St. Edmunds will apply for a provisional order empowering them to lay down mains and plant, and charge for current supplied, and also to make agreements with companies and persons for supplying electricity. The Corporation of St. Pancras and Hastings have similar powers.

The Telegraph Construction and Maintenance and the West London Electric Lighting Companies work has recently supplied the Swan electrolizers for the statement, G. H. H.M.S. Orontes, are now making a similar class of fittings for the White Star Ice Steamboats. The same firm has just completed the electric fittings for Mr. W. S. Gilbert's house at South Kensington.

The Westminster District Electric Lighting Company have given notice of their intention to apply to the Board of Trade next session for a provisional order to supply electricity within the district of the Westminster Board of Works. The area comprises Vauxhall Bridge-road, Grosvenor-road, Horseferry-road, Victoria-street, Tothill-street, Queen Anne's Gate, Birdcage Walk, the Mall, Pall Mall, Cockspur-street, the Government offices, the Houses of Parliament and the Government buildings, Whitehall-place, Scotland-yard, Northumberland-avenue, Trafalgar-square, and Prince's Gardens. Suitable powers will be asked for carrying on the works.

The electric lighting station at Brixton, which was established by the Metropolitan Brush Company, has been leased to Messrs. Clark and Co., who are now feeding forty-seven arc lamps and ten incandescent lamps from a forty-light Brush machine. They have discontinued the use of the greater part of the Brush lamps, and have replaced them by Clark and Bowman lamps, which give a very superior result, and will be supplied with self-trimmings with any lamps in the market. Clark, Bowman and Co. have also illustrated candelabra, brass lamps in daily use in the room like we may help create that the same two-holder has a positive feed, and is reversed by a current sent into it by a relay, which has no other effect to perform, and therefore responds readily to any change of resistance in the arc. The feeding takes place with great regularity at intervals of about fifteen seconds, and if it be assured that the movement will be one of an inch, the lamps are let to the neighbouring sleepkeepers at a rental of ten shillings a week, and it is stated that a good profit is realised at these terms.

The first ordinary general meeting of the Swan United Electric Light Company was held on Tuesday last. The chairman, Mr. J. S. Forbes, stated the business of the company had been chiefly in the manufacture of lamps, and that it was probable it would increase next year. The attention of Mr. Swan and Mr. Sievey was being directed to further improvements, and it was to be expected that they would derive great profits from this branch of their business. They would not be injured by their assignment with the Edison Company, and on the other hand they would share in any benefits which might be effected from their patents. Owing to the novelty of the enterprise and the great consumption of the old companies, their progress in other directions had not been so great as would otherwise have been the case. It was a question whether they should not discontinue making detached installations at present. Some of those already erected had not paid, although they had been useful as advertisements, and it would be better in future to receive their value "out and out." Several cases in the metropolis had been secured for lighting districts, and the installation at Victoria Station was looked forward to with great interest, as it would prove whether isolated-source lighting could be done on a large scale as a profit. The sum of 50,000*l.*, which included the whole of the preliminary and other expenses, had been charged against the year's profits, and had reduced them very considerably. The directors were now in possession, a waiting game, and were watching to see in what direction they could develop the business with advantage.

Electrical World,
April 19th 1884.

St. Johns, Quebec, to be Lighted.

Some years ago Messrs. A. Perry, of Montreal; Chas. Archibald, Alex. Macdonell, G. H. Wilkinson and A. Beaucage, of St. Johns, Quebec, associated themselves together for the purpose of organising a gas company in St. Johns, Quebec, and accordingly like $10,000 was subscribed, but this beleaguered sufficient to warrant the directors to go to an allowance the scheme was abandoned and the town seemed forever doomed to darkness. Dr. Gustavus Griffin of the Phœnix Electrical Company for Canada, opened negotiations with the City Fathers about three weeks ago, says the Montreal Witness of the 7th inst., and seeing the need of light offered to supply thirty arc lamps of two thousand candle power each, to be placed on the streets and to supply his company's system of incandescent lamps for stores and private use at a five cents per light per night. So much encouraged was Dr. Griffin that he gave a free exhibition of both the arc and incandescent lights in the Messrs. Macdonald Stone and Chinaware Company Works and in front of the St. Johns Hotel, which was witnessed by more than half the entire population. After the exhibition was over negotiations were opened with the mayor and aldermen to supply the arc light for street lighting and with Louis Molleur, Esq., president of the Banque St. Jean, to supply the incandescent lamps for the merchants and private use, as he had a gas engine at his water works lying idle. Mr. Franklin H. Smith, president of the Phœnix Electric Company, received a telegram on Saturday afternoon last from Dr. Griffin stating that he had closed with the authorities for 2,000 incandescent lamps to be used in lighting the streets as well as the houses, and that more than 200 lights had been signed for by the merchants on Richelieu street. On receiving this news Superintendent McConnon, of the Phœnix, left to assist Dr. Griffin in swapping out the plans for lighting, etc. The Phœnix has received the first contract ever awarded to any company for lighting a town in the Dominion exclusively by the electric light. President Smith with his superintendent, Mr. McConnon, will visit St. Johns during the week to commence the work of laying on the wires and putting up the lamps. This is probably the largest contract ever awarded any company in the Dominion. It looks as though electric lighting will soon be brisk throughout Canada.

most effectual method of raising the cage to the height required for the various floors in use.

The committee being composed of practical men of business, were soon convinced of the necessity of throwing their preconceived opinions to the winds, and without loss of time following the advice of Mr. Abernethy and Mr. Williams, determined upon remodelling the scheme upon the lines of Mr. Williams's report, and gave the necessary instructions to prepare plans, &c., for depositing this autumn, so that the sanction of Parliament might be sought at the first possible opportunity. This decision was arrived at in the latter half of October last, and as we have before mentioned, the necessary notices have been issued, and plans deposited in compliance with the Standing Orders of the two Houses of Parliament, and ere this bill we may expect the great Parliamentary fight of next session will take place.

We are told that in 1824 a bill was promoted in Parliament for making a ship canal to Manchester. The proposed entrance was on the Dee, crossing by Parkgate and Saney by Frodsham, Runcorn, Lymm, Altrincham to Manchester. The scheme was most strenuously opposed, and thrown out, it is said, through not having complied with Standing Orders. In all probability, it was hastily advised and ill considered, and no doubt justly deserved its fate.

THE ELECTRIC LIGHT COMPANIES.

We have received from the publishers of the *Mercantile Shipping Gazette and Commercial Review*, of 65a, London-street, Fenchurch, a copy of their second annual supplement, which this year is devoted to an account of the constitution, progress, and resources of all the electric light companies, with explanatory tables and remarks. The value of having a financial history of the companies from their birth, if properly prepared, and even approximately compilation it is difficult to speak too highly, for although it has been kept within a moderate compass, put every line represents considerable patient labour and research, not only among prospectuses, ments and documents filed with the Registrar of Joint Stock Companies at Somerset House, but also in other and more private directions. The task of wading through a legal document, in which the respective positions of vendors, promoters, and shareholders are carefully defined is that undertaken by few, and which, if done by the ordinary individual and the despair of the laity, is sufficiently formidable to deter, but when it has to be done for ninety companies, many of which are related to each other in a single or double way, the difficulty enormous, and when accomplished deserves the recognition of the public. In this case we have no doubt that both electricians and commercial men will be much obliged to the *Mercantile Shipping Gazette* for the publication of this supplement, as there has long been a very eager curiosity to learn the success of the electric companies, and a fear that rumours have been afloat as to the amount of money subscribed by the public, and that many who have gone into investors' pockets, but no definite comprehensive statement has been issued until the present, and now we see how largely exaggerated have been the statements that have been put forth and accepted even by moderate men.

The chief portion of the matter of the supplement consists of a list of all the companies, arranged alphabetically, stating the date of formation, with the registration number. Under each company there are given, wherever the particulars are available, details of the nominal amount of the company's capital, of the number of shares allotted as fully or partially paid up in payment for the public, and of the arrangements whereby the property, patents or other, was transferred from the original vendors through the intermediate promoter or syndicate. In some cases the companies having purchased plant, have since formally wound up. In others an unsuccessful issue may be inferred from failure to fill the register of shareholders, or even notice of the office of the company, although this occasionally is no doubt simply the result of neglect. As the size of the offices has been to adhere rigidly to facts, and to avoid making invidious distinctions by appertioning praise or blame, the particulars are left to speak for themselves without comment; but to facilitate comparison and the formation of a just conception as of the whole, the leading facts have been summarised in the form of tables, of which we give one that will, we think, be found by our readers to be replete with interest. The Table is divided into four sections and a summary; the first deals solely with the British Companies, of which there are no less than twenty; the second relates to companies that are nationally at work, or prepared to work, and of these there are twenty-three, or only three more than the British list; the third refers to companies that do not appear to have been proceeded with particularly; and the fourth to companies mostly recent, about which information is wanting or not yet attainable.

The first point to which attention is called by our contemporary is the extent of shares and debentures issued, 7,888,440*l.*, or 45 per cent. of the nominal capital of the companies comprised in Groups I. and

SECTION I.—BRITISH COMPANIES.

ELECTRIC LIGHTING MEMORANDA.

Two shareholders of the Electrical Power Storage Company have held their annual meeting, at which the usual tale of disaster had to be told. This is the only rival to the Faure Accumulator Company, whose troubles have recently been mentioned in these columns; and is not in much better case than the hybrid French-English speculation which it is supposed to have relished of some valuable inventions. The loss of the Company on their year's working is set down in the balance-sheet at £19,765; but *Money* says these figures are perfectly illusory, and gives the loss at £56,581 for the year, with a deficiency, on the general balance-sheet, of £520,810. This is a melancholy state of affairs; but yet the meeting passed off fairly well, although the capital was reduced from £800,000 to £200,000, or a clean sweep of three-fourths of the shares. This most drastic measure was pleasantly recommended from the chair in decidedly novel terms. The Chairman said that the proprietors would receive a new £1 share for every two £2 shares, and "as the capital was fully paid, it was really immaterial to the shareholders what the nominal amount of each share was." That is to say, if a man gives £4, and gets a receipt for a sovereign, it is all the same. Of course it is in this sense in regard to the Company; for when the inevitable smash comes, the nominal value of the shares will be of small moment to the unfortunate holders; but this cannot afford much permanent satisfaction to people who place their money in a concern that will keep going until all the capital is run through, and then stop.

The question of overhead wires for all kinds of electrical circuits has not attracted in England so much attention as it has abroad, and especially in New York, where the clusters of wires along the streets are not only an eyesore, but frequently denoted for the possible dangers of breakages and even of contact. Yet it is undeniable that the matter is of overhead of England; and it is not surprising that, as announced, the Government have decided to move for the appointment of a Select Committee of the House of Commons to examine into and report upon the whole subject. The initiative has been taken by the Post Office authorities, who are probably anxious that the interests of their own Department shall not suffer from the multiplication of wires.

There seems to be a considerable amount of free-trade in incandescent lamps; for, notwithstanding the claims of the great patentees, Swan and Edison, to say nothing of the claims of second magnitude, such as Maxim and Crookes, which, as they contend, are not only equal to, but infinitely surpass the wares of the world-renowned Company, there is a considerable sympathy with the smaller manufacturers, who, while the great people already named are losing money by tons of thousands a year, are quietly continuing to do a remunerative business, and make and sell electric lamps for as they would make and sell parasite lamps—as a matter of trade. If there is anything like a popular demand for electric lighting, it is probable that these minor manufacturers will reap the benefit of it, after the inflated joint-stock concerns have run their allotted course. It has been seen how the installation of arc lighting at Paddington, that came to grief in the hands of the Metropolitan Brush Company, has been more successfully worked by local people; and now, in respect of incandescent lighting, Messrs. Woodhouse and Rawson have issued a circular, in which they offer to supply lamps of 80 per cent. higher efficiency than the ordinary Swan lamps, at about 2s. each for 16 and 20 candle power. According to this statement, electric lighting *per se* will not suffer much from the proximate extinction of all the stock-jobbing speculators who have hitherto claimed a monopoly of interest in the matter.

Bradstreet's (N.Y.) Feb. 1884.

If economy were the sole consideration the future of the incandescent light in England would be far from encouraging; but, happily for its production, it possesses so many and important advantages that, despite its higher price, it is in no danger of losing the ground already gained and of failing to make substantial advances. The demonstration of experience, therefore, that it cannot compete with gas on an economical basis causes no apprehension on the part of its supporters. The London *Engineer*, in a recent issue, after confessing that it is dearer than gas, asserts its belief in its future well-being, and various other journals have expressed themselves to the same effect. The *Engineer* says: "As to the future of electric lighting there is no room for doubt. It will succeed. The inherent merits of the light are so great that it cannot possibly be dispensed with, and, under the most adverse circumstances, it is steadily pushing its way. . . . Electricians may take heart. Bad as their prospects are just now they can rest assured that there is a good time coming for the light which they advocate. But fortunes will neither be made nor lost in a hurry, and this is the best guarantee that the electric light will enjoy public favor and commercial prosperity." In this country also the merits of the light rather than the cost is being increasingly urged as the chief consideration, but there is less need for this mode of advancing it here than abroad, and in time we may expect to see this need wholly disappear.

While ...ts are provided for, special ...ired upon the warming and ...ratuses, each court being ...regards its heating and air-...each there is a chamber ...compartments; in one the ...d to warm and maintain the ...courts to a temperature of from 55 deg. to 60 deg. in the coldest season, with an interchange of air, equal ...to something like 10,000 cubic feet per minute. In ...other compartment is used for cold air. These two ...chambers merge into one, and are covered with ...fine cotton cloth, which is used for misting and ...filtering the air before it passes into the court ...through numerous vertical openings provided behind ...the wall linings, as well as other convenient points. ...The entrance to these two compartments is under ...control from the lobbies in the court, so that the air ...driven in by the fans can be shut off through one or the ...other or partly through both, and can be regulated ...at will to suit every condition of the atmosphere. The ...supply of air, which in summer is calculated to reach ...the total volume of cubic feet per hour, is drawn from the whole of the areas surrounding the ...Great Hall, and is freed from dust and smut by being ...passed through a fine water spray. The withdrawal ...of the vitiated atmosphere is accomplished by means ...of powerful steam coils placed in the ventilating shafts, ...to which access is given by numerous openings in the ...ceilings and galleries. Thus far the arrangements we ...have described have been for the purposes of warming the building. It was felt, however, that it ...would be necessary to cool the air in hot weather, as ...well as to circulate it, and for this purpose an entirely ...distinguishing machine has been erected on the roof, ...consisting of a pair of engines, vapour pumps, refrigerators, and condenser. This machine is of ...sufficient power to receive 1000 gallons of water ...per minute from 72 to 40 deg. Fahr. The water thus ...received is converted in five sprays by an "ejector," and the cool vapour through the coils. The cold water ...that is not absorbed is collected in a cistern, and conveyed to the condenser, where it is used to obviate the ...heat given off by the ether in liquefying, and is finally ...allowed to escape at a temperature of 70 deg. A recording thermometer is attached to the inlet and outlet pipes of the cooler, so that the temperature of the services under the system can be regulated accurately. The works have been executed by Messrs. Haden and Sons, of Trowbridge, and carried out under the supervision of Mr. Frederick Blake, of Manchester, who assisted the late Mr. Street in working out the scheme.

ELECTRIC LIGHTING NOTES.

At the present time, when the relative costs of combustible gas and electricity are keenly debated, a pamphlet entitled "Electric Lighting by Water Power," and bearing the date 1883, cannot fail to attract attention. Whether the author, Mr. T. B. Grierson, who considers of this when he republished the paper which twelve months ago he read upon this subject before the Institution of Civil Engineers of Ireland, we do not know, but after a perusal of its contents we cannot help thinking he must have had a glimmering perception of the facts. If not, we are at a loss to understand why he now ventures to transfer it from the small circle, for which it was originally intended, and offer it to the public.

Even twelve months ago it received a good deal of sharp criticism from the meeting to which it was addressed, at least so we gather from the tone of the reply which is bound up with the paper, and a great many things have happened, from an electrical point of view, during the past year. We have been unable to decide whether it was electrical science or the utilisation of water power, with which Mr. Grierson professed to be familiar, which we undertook to prepare his composition. We suppose it must have been one, and we presume he would purport to learned societies on subjects with which they are not acquainted.

Now, instead of a description of the Brush apparatus, we can find room on our columns, the only information we can find relating to electricity beyond the normal commonplaces, (1) that although the Jablochkoff candle was a most beautiful and simple arrangement, (2) "the reversals of the current was an troublesome and inconvenient in the case of the lamp, was in many cases discontinued in consequence," and (3) that Faraday discovered "the principle by which to generate a current of electricity by rapidly passing wires between the poles of powerful steel magnets." It must be confessed that these two assertions, although not without a certain amount of originality, do not convey the idea that the author is perfectly acquainted with the theoretical and practical aspects of electric lighting. What he says about water power is certainly correct, but by no means novel. No one doubts that "the turbine is one of the most, if not the most, economical of water motors of the present day," or that an abundant supply of water must always be the cheapest power in the generation of electric currents to be utilised in the immediate neighbourhood. Now, we do not complain of Mr. Grierson having presented a paper of little value to his own society—it appears to have elicited a lengthy discussion, and, in so far no doubt, served a useful purpose—but we think when he undertook to instruct the public he might have taken the trouble to ascertain what was being lit up to the enormous standard of wattage upon the subject. It is possible that a local interest in the matter has been excited in Dublin by exhibitions for international orders under the Electric Lighting Act, and if such be the case information bearing on the matter will be greatly in request. If that be so there was every opportunity for our author to have done a service to his fellow citizens. He mentions at least two possible sources of water power in Dublin, and he would not have been difficult to have formed a rough estimate of the probable amount of power from each, and to have given its equivalent in candle power under the various systems of arc, incandescent arc, and incandescence lamps. A page devoted to details of this kind would have more value than twenty of generalities, for the battle of electricity *versus* gas is being fought upon points of detail, and if our author can show a cheap and sufficient supply of water power in Dublin he will render a better service to the interests of the gas company than he has done by the publication before us.

The Faure Accumulator Company was formed about

ELECTRIC LIGHTING NOTES.

We notice that the Gloucester County Lighting Association have acknowledged the fitness of the electric light for every-day use by adopting it in their new asylum. This large building is going to be lit with incandescence lamps, and the work has been entrusted to Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street. The motive power will be supplied by Otto's gas engines run with Dowson's gas. Fares, Sellon, and Volckmar accumulatory batteries, and Woodhouse and Rawson incandescence lamps will be employed.

The s.s. *Clan Macarthur*, which has been built for Messrs. Ogilvy, Gillanders, and Co.'s Clan Line, by Messrs. Scott and Co., of Greenock, started from the Clyde on Saturday last for Natal, for a preliminary cruise with a large party on board. The vessel has been lit throughout with the Swan incandescent lamp by the Glasgow Incandescent Electric Light Company, who will undertake that the owners have no further trouble with the complete system obtained, that they have placed the lighting of another steamer, the *Macindoe*, with the same company.

We understand that the order for the lighting up of the Huddersfield Technical Schools Exhibition has been secured by Messrs. Kingsford and Smith, of Leeds, agents and district managers for the "Yorkshire Brush" Company, and Messrs. Fernald, Thompson, and Ince, Limited. A 40-light Brush machine will be used for lighting up the weaving and other sheds by arc light, while a 200-light Fernald dynamo will be used for feeding incandescence lamps in the rest of the building. This Exhibition, which will be similar to the one held at Bradford last year, is to be opened by the Prince in July, and is expected to remain open till about November.

The Electric Light Contract and Maintenance Company, which lately went into voluntary liquidation, has paid a first dividend to its shareholders of 1l. 15s. per share, the result, after all up to date. It is expected that a second dividend of about four shillings per share will follow, and thus the subscribers will practically receive the whole of their money back again. The company was started with the view of supplying electric light in the same way that a gas company supplies gaslight, and has adhered rigidly to its programme, steadily refusing all offers of amalgamation and declining to undertake any business that did not rest upon a commercial basis, that is, which did not promise to give a profit. The result has been that the company has done nothing whatever, and has not lighted one solitary additional lamp. The liquidator has received a powerful corporation, managed by so influential a board, and provided with ample capital, remaining in a state of repose for twelve months, and finally wisely declines to do business on such conditions as obtained, signifying, as it confirms the idea that the electric light, although a fine field for speculation, is not at present a subject for the genuine investor.

Mr. Lane-Fox's patent for the employment of secondary batteries in electric lighting, which dated October 3, 1878, came before the Solicitor-General on Friday, but as none appeared in opposition to the application for the revocation from his patent all the claims originally made by him, except that which covers the employment of secondary batteries in combination with parallel arc distribution, as described in his specification. His application was opposed by the Swan United Electric Light Company, Messrs. R. E. Crompton and Co., and the British Electric Light Company, upon various grounds, among which were that the invention to which Mr. Lane-Fox wished to limit his patent by the proposed disclaimer was not a novelty, that it was not sufficiently described in the provisional specification, and that the proposed disclaimer would alter the character of the patent. Mr. Wilkinson, Q.C., and Mr. Moulton (instructed by Messrs. Graves and Humphreys, solicitors, for Mr. C. C. Mewburn, patent agent), appeared for Mr. Lane-Fox in support of the disclaimer, Mr. Aston, Q.C., and Mr. Chadwick Healey (instructed by Mr. F. H. Johnson, solicitor), appeared for the Swan United Company, Mr. Aston, Q.C., and Mr. Phipps (instructed by Messrs. Brooks and Son, patent agents), for Messrs. R. E. Crompton and Co., and Mr. Carpmael (instructed by Messrs. Wilson, Carpmael, and Edgerton), solicitors for the British Electric Light Company, Robinson in support of the disclaimer was given by Mr. Aston, Professor Stevens, Professor Fleming Jenkin, F.R.S., Professor Silvanus Thompson, Mr. Preece, Mr. R. Sabine, and in support of the opposition by Mr. J. W. Swan, Mr. R. E. Crompton, Dr. Hopkinson, F.R.S., Mr. W. H. Preece, F.R.S., Professor Ayrton, F.R.S., Professor Oliver Lodge, Mr. D. G. Fitzgerald, and Hon. R. Brougham. After a long hearing the Solicitor-General decided to grant Mr. Lane-Fox's application for leave to disclaim. The claim under this patent will therefore be for the employment as described in the specification of secondary batteries, as conveyers of electricity in combination with a mode or system of distribution such as is therein explained.

Engineering, June 16, 1882.

JOEL'S ELECTRIC LIGHT.

This promising illuminant has been fitted up in the offices of the Prudential Assurance Company, Holborn-bars, by Messrs. Rowatt and Fyfe's Electric Light Company. One-half of the extensive upper floor is lighted by one Joel lamp of 160 candles-power each, and those replace 45 gas jets. The other half of the floor is still lighted by gas, and the contrast is very striking in many ways in favour of the electric light exhibits the various insurance cards in their true colours, a matter of convenience to the working staff, and it enables the atmosphere to be maintained far more fresh than under the old system of gasburners. Joel's lamp is an improvement on that of Werdermann, which has been installed in the Paris Opera House, and is well adapted for lighting offices. The burner consists of a pointed pencil of carbon resting on a knob of copper. The positive current flows from the carbon to the copper rod in doing so heats up the fine carbon point to incandescence. But there is also a small shadow-box at the junction of the carbon and the copper which greatly increases the intensity of the light, without appearing to detract from its steadiness. It is, therefore, intermediate between the proper arc light and the purely incandescent light of Edison, Swan, Maxim, and others. The lamp is not so small and handy as these lamps are, but its greater power is an advantage for some purposes. At the Prudential Assurance Office the nine lamps are fed by a B Gramme machine of low tension, driven by a 20 horse-power steam engine kept on the premises; but the energy absorbed is estimated at 35 horse power. According to the report of Professor W. G. Adams, the Joel system is capable of yielding a light of 715 candles per horse power.

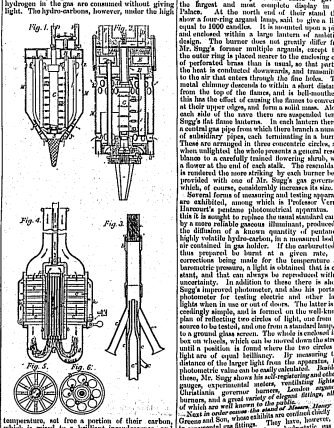
establishment were 10222, and salaries and wages 2960l., the balance in hand at the end of the year being 963l. or 193l. more than at the commencement. A legacy of 1000l. (less duty) has been left to the Council by the widow of Mr. Henry Robinson Palmer—well known to the late generation of engineers as Telford's chief assistant—for the foundation of a scholarship at Cambridge University, the gift to be by the son of a civil engineer who may need help, and who should be nominated by the Council of the Institution.

A society blessed with ample funds and an active executive, should have little cause for anxiety, but a successful past demands an equally successful future, and so we find the Council still canvassing for communications of a complete and comprehensive character. A light of thirty-eight subjects is published to show how catholic is the taste of the Institution, and to serve as hints to members and others whose position or experience has given them special opportunities of acquiring knowledge in any of the many branches of engineering science. It is not only to the *esprit de corps* of the members, or to their zeal for the diffusion of knowledge that the Council appeals, for it sets forth a list of annual premiums, medals, and prizes at its disposal for approved original communications submitting to the value of 467l. Looking to the number of members, and particularly the large proportion of young life, much of which is engaged in active research of some kind or other, there should be no lack of valuable contributions. To Mr. James Forrest the Institution is so much indebted, for the individual services so freely and untiringly rendered to its members, and to the engineering manner in which its business is conducted, and its Transactions published, that it seems to us that every year, the welfare and prestige of the Society become more and more dependent upon its secretary.

THE CRYSTAL PALACE ELECTRIC AND FISHERIES EXHIBITION.

The Electrical Exhibition at Paris continued late into the autumn of 1881, and scarcely was it closed before active preparations were made for that at the Crystal Palace. From midwinter to early summer exhibitors were busy, and during that time many were called away to Munich to maintain their claims to precedence in Germany. And now, again, almost before they have fairly returned, the Crystal Palace Company urges them to repeat the show that last winter proved so remunerative to the shareholders, and so attractive to the public. But there is a limit even to the patience of inventors and to the claims of electricians, and consequently to most of the leading companies are not represented at the Palace. Some, as Siemens, have already appeared since the spring; several millions of pounds sterling have found their way from the pockets of the public into those of patentees, and of their friends the promoters, and systems of electric illumination, which then had little beyond their merits, or the eloquence of their partisans, to recommend them, are now upheld by rich corporations. Those reasons of themselves would be sufficient to account for the absence of many of last year's exhibitors, but there is a still more powerful one to be found in the operation of the Electric Lighting Act, which has evoked a host of applications for Provisional Orders, and all those interests that are devoted to do business on a large scale, have their attention set upon schemes which they hope will prove more profitable than instructing the public. To make up the deficiency in the electrical part of the exhibition, and to stimulate the feeling of competition that always attracts the public, recourse has been had to gas; the Palace has been equally divided between the two illuminants, and a fair field offered to each in which to vie with its rival. The unsatisfactory of gas lighting apparatus have responded warmly to the challenge, and all the well-known firms have already commenced their coatings with an energy that should command success. The south nave and its precincts, which is the area allotted to gas, is a blaze of light, every notest burner, and some that have only lately been brought before the public, being represented. The north nave on the other hand is, for the present, almost dark, and although the catalogue presents a very respectable list of firms who are eventually to join in its illumination, most of them have yet failed to give any sign of their presence.

Deferring our notes of the electrical exhibits until they shall be more complete, we shall confine our remarks this week to the older and more successful competitor, gas, and shall begin our examination at the junction of the south nave with the centre transept, where we enter one of the areas lighted by the Siemens Patent Gas Company. It is but little more than two months since we illustrated and described the new regenerative gas burners of Mr. Frederic Siemens (see page 328 of the present volume), it will be needless to do more than recall to the minds of our readers the fact that they depend for their action upon the temperature of the gas not being raised, while on their way to the point of combustion, but upon an intense heat being maintained in the neighborhood of the flame. During combustion the hydrogen, carbonic oxide and unconverted hydrogen in the gas are consumed without giving light. The hydro-carbons, however, under the high



temperature, not from a portion of their carbon, which is raised to a brilliant incandescence, and affords the illuminating power. As the temperature increases so does the brilliancy of the flame, which at 2050 deg. Fahr. assumes a very white hue, and the lowest cost of the light. The rate of consumption at which we have referred, shows that the power of the lamps varies from 5.5 to 7.2 cubic feet per cubic foot of gas burnt per hour. There are 1000 burners suspended in the south nave, each consuming 85 to 90 cubic feet of gas per hour, and each giving a light of about 600 candles. The cost of their gas per hour, at 3s. per 1000 ft., is 3d. each, or 4s. for the whole of them. The roof of the concert room is lighted by three lights of a similar size, and also by five smaller lamps, each consuming 50 cubic feet per hour, and giving 330 candles light. The hourly cost of the latter is 1.5d. each. Those who have not seen the Siemens burner since it was shown at the Smoke Abatement Exhibition, will notice with pleasure the great improvement that has been made in its appearance by the removal of the two unsightly side flues by which it was formerly discovered. The chimney, instead of being bifurcated and led outwardly to the lower part of the burner, is now carried down in its centre, and, as its diameter is considerably reduced a short distance above the flame, the lower portion is scarcely noticeable. Of course this does not remove the old objection that a massive body of the burner is of considerably larger diameter than the annular flame, and that consequently there is a large area of floor space below the lamp that is only lighted by reflection from the under side of the cornice.

In close proximity to the Siemens Company are Messrs. Williams Sugg and Co., Limited, who maintain their reputation and continue their enthusiastic advocacy of the cause of gas by the largest and most complete display in the Palace. At the north end of their stand they show a four-ring argand lamp, said to give a light equal to 1000 candles. It is mounted upon a pillar and enclosed within a large lantern of noticeable design. The burner does not greatly differ from Mr. Sugg's former multiple regenels, except that the outer ring is placed nearer to the enclosing case of perforated brass than is usual, so that part of the heat is conducted downwards, and transmitted to the air that enters through the fine holes. The metal chimney descends to within a short distance from the top of the flame, and is bell-mouthed; this has the effect of causing the flames to converge at their upper ends, and form a solid mass. Along each side of the nave there are suspended ten of Sugg's flat flame batswing burners. In each there is a central gas pipe from which there branch a number of subsidiary pipes, each terminating in a burner. These are arranged in three concentric circles, and when unlighted the whole presents a cluster of gas blusos to a carefully trained flowering shrub, with a flower at the end of each stalk. The combustion is rendered the more striking by each burner being provided with one of Mr. Sugg's new governors, which, of course, considerably increases its size.

Several forms of measuring and testing apparatus are exhibited, among which is Professor Vernon Harcourt's pentane photometrical apparatus. In this it is sought to obtain the usual standard candle by a more reliable gaseous illuminant, produced by the dilution of a known weight of pentane, a highly volatile hydro-carbon, in a measured body of air contained in a gas holder. The carburetted air thus prepared be burnt at a given rate, due corrections being made for the temperature and barometric pressure, a light is obtained that is constant, and that can always be reproduced without uncertainty. In addition to these there is shown Sugg's improved photometer, and also his portable photometer for testing electric and other large lights when in use or out of doors. The latter is exceedingly simple, and is formed on the well-known plan of reducing the intensity of the rays from the source to be tested, and one from a standard lamp, on to a ground glass screen, by the inverse squared law's box on wheels, which can be moved down the street until a balance is found between the two circles of light are of equal brilliancy. By measuring the distance of the lamps from the screen the candle-power is readily calculated. Besides photometers, Sugg also shows his self-registering and other gauges, experimental burners, ventilating lights, Christian's governor burners, a variety of elegant fittings, all burners, and a great variety of *bijouterie*, some of which are well known to *Engineering* readers.

Next in order comes the stand of *Messrs. Henry Greene and Son*, whose exhibits are confined chiefly to chandeliers and fittings. They have, however, constructed a gas fire for a hydraulic gas two novelties; the first is the usual diaphragm or floating governor is replaced by a bellows that constantly fills the valve, is replaced by a bellows that constantly fills and empties the bellows, and in so doing figures accompanying the notice by which the gas pressure is regulated. The first shows the valve which commands the inlet to the bellows, and the pipes which communicate with the gas pipes from which an exceedingly simple form of governor is constructed. The second illustrates the governor gas burner, and is described in detail in Messrs. Greene and Son's pamphlet on the subject. The first consists of an ordinary argand chimney, or cylinder, of glass, but within a second chimney, or cylinder, of the same form, of larger diameter, but shorter in length. The space between the two is filled with air by the outer chimney descends to the bottom by a circular burner, and is then carried to support the inner chimney. The air thus drawn there through a mass of narrowly glass tubes before it can reach the combustion two glasses before it can reach the between the two is thereby heated, and thus rendered less dense. In passing it becomes greatly heated, and

ELECTRIC EXHIBITION AT KÖNIGSBERG.

It will be new to the greater number of our readers to learn that an electric exhibition has been open at Königsberg, in Prussia, since the end of April. It was projected with the view of giving to the population of a large district, separated by many considerable distances from the central and more favoured parts of the kingdom and empire, an opportunity of becoming familiar with a subject of which, under other circumstances, they must have remained ignorant, as they are but little accustomed to travel. Königsberg, a strongly fortified and university town of 123,000 inhabitants, stands on the Pregel, which goes to the Frische Haff, one of the bays of the Baltic; it is the capital of the province of East Prussia, which has plenty of lakes and forests, but, if we except the coasts and the rich and fertile districts of the Vistula delta, a sterile soil, and a scanty, poor population.

The nearest large town, Dantzic, is 130 miles distant, while Berlin is more than 300 miles. To the south there is Poland, with its single important and capital town of Warsaw, at 160 miles distance; and on the coast there are those parts of Russia which have a strong German element. To start an electric exhibition at Königsberg is no less an undertaking than similar perhaps in the case of Aberdeen. But such an exhibition may serve the interests of both the public and the manufacturer just as well as some of those which have taken place in more important towns. There was no Crystal Palace available at Königsberg; but suitable accommodation has been obtained in the public gardens belonging to the town. A fine Renaissance building has been erected and tastefully furnished to show the various appliances of electricity for its different purposes, and most of the fourteen groups into which the exhibits are divided, have been entertained in special pavilions. The historical and educational group occupies, besides others, the very valuable collections of scientific and technical instruments of the university and various institutions of Königsberg; one section has been assigned to the medical group; further, a very instructive and complete reading-room has been established, to which nearly fifty of the leading publishing firms of Germany have contributed copies of their respective works and periodicals. Batteries, &c., have been supplied by eighteen exhibitors; telegraph apparatus by various firms and the Eastern Railway, which is under Government management, like most of the important German lines; there are more than forty persons employed as light-meclinists, besides a number of others for electro-plating; for these, fifteen steam and three gas motors are at work, and there is an several hand dynamos. To illustrate the illumination of ships, a ship's skeleton 200 ft. in length by 60 ft. in width has been erected. There is telephonic communion with the Königsberg opera, an electric railway, and of course no lack of refreshment rooms. The apparatus which, with the help of the electric light, is to illustrate the diving opera, is under the direction of Mr. Siemens, and consists of a number of hermetically tight or smaller quantities all along the south and east coast of the Baltic, but mainly in the rectangular peninsula of Pomland, which on the north lands on the River Pregel, on which on the north lands on the River Pregel, on which Königsberg is situated; stretches from east to west into the Baltic between two of its bays, the Frische Haff and the Kurische Haff. The valuable coast of which it is washed by the sea, carrying it towards the shore where, especially after a rough wind from the west, there is a rough searching, and formerly the only source of this trade, which is known in most ancient times; in which, it appears the name "Electrum," it was the first object, under the production of electrical phenomena. There is no record of this manner in which it was carried to the more civilised parts of the world, but probably the Phœnicians obtained it with other products by overland trade, and that they did not, as has been asserted, send their ships all round Europe and Africa for the amber and sifting the clay in digging for the amber and sifting the clay in the sea thrown out voluntarily or by tides to the river.

ELECTRIC LIGHTING.

The Victoria Station, Manchester, in the joint occupation of the Lancashire and North-Western and Lancashire and Yorkshire Railway Companies, is the scene of an interesting durable installation of the electric light. From the centre of the main platform may be seen on one hand the Brockin lamps of the British Electric Light Company, and on the other hand the alternate current lamps of Messrs. Siemens Brothers, and an opportunity is thus afforded of comparing on an extended scale the merits of the two rival systems and their relative adaptability to railway illumination. The British Electric Light Company employ two B Gramme machines, driven by a 20-horse power engine, and their arrangements follow the general plan adopted by them elsewhere. Messrs. Siemens Brothers feed nine lamps from a small alternate current machine and an emitter actuated by a pair of Tangye's three horse power engines. The method of driving is, we believe, new for the purpose. In each adapted to receive a three-quarter inch discmeter rope, and in the gullyes of the alternate machine and of the exciter there are respectively three and two such grooves. A single driving rope is carried round the pulleys much in the same way, as if they were a pair of five-sheave pulley blocks, the two lower pulleys representing the lower block, and the coils of the rope being tied together. The lamps are hung from the roof by cords and counterweights, and are so suspended that the act of drawing any one of these down first short-circuits the leading wires, and then removes the lamp out of electrical communication with the machine. The arrangements in the London and North-Western Company's station have been carried out by Mr. Haworth, Messrs. Siemens Brothers representative in the North.

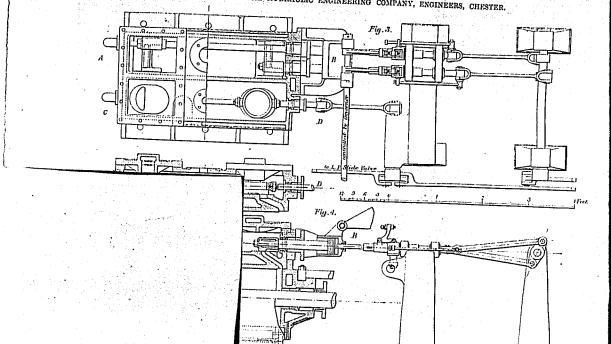
Engineering, June 30, 1882.

THE ELECTRIC LIGHT AT STAFFORD HOUSE.

The Duke of Sutherland has set a good example in adopting the electric light for the illumination of his residence in St. James's. Seven lamps on the Lane-Fox system have been installed in the grand staircase, hanging-hall, and picture gallery, with very fine effect. The lamps have been fitted to illustrating lunches fastes hours as far as possible, but additional lamps have been added, especially in the picture-gallery. There are some 250 lamps in all, for six B Gramme machines, which are excited by the current from one E Gramme machine, which would suggests of the B machines are fed in series; but the revolving rings are not coupled in multiple arc. The resistance of the external circuit, plus the lamps, is only 3.6 ohms, the lamps being connected in parallel arc, and loads having a strand conductor equivalent to a solid rod of copper 7 in. in diameter being employed. The speed of the machines is about 1900 turns per minute, and they are driven by a Marshall engine of 20 horse power nominal. All the generating apparatus is located in a shed placed in the garden to the west of the house, and skirting the Green Park. The lamps displace some 8000 candles, and cannot be injurious to either gilding or stuffs. In fact, together with the undoubted sanitary advantages of the incandescent light, cannot fail to hasten its introduction into sumptuous where assemblages are held. The Duke of Sutherland's example will doubtless soon be followed.

HYDRAULIC PUMPING ENGINE AT THE WEST DOCKS, HULL.

CONSTRUCTED BY THE HYDRAULIC ENGINEERING COMPANY, ENGINEERS, CHESTER.



ELECTRIC LIGHTING NOTES.

MESSRS. FARADAY AND SON have lately brought out two enlarged Swan lamp fittings with safety fuses for factory use. These have been applied successfully in some of the largest cotton factories in the north. Messrs. Faraday are also engaged on some special fittings for Messrs. Simons Brothers at the Perth Bridge works.

The Yorkshire Brush Electric Light and Power Supply Company, Limited, and Messrs. Furnell, Thompson, and Lee, Limited, will in the future be carried on by the Hammond Electric Light and Power Supply Company, Limited, with which the above mentioned companies are now amalgamated. Mr. Thomas Smith is their agent and representative for Yorkshire; the Yorkshire office being at 1, East Parade, Leeds.

An Industrial Exhibition was held last week at Hampstead, in Hampshire. In order to enable the exhibition to be kept open at night, Messrs. Woodhouse and Rawson instituted a temporary installation of six Pilsen arc lamps, driven by a Pilsen dynamo and dynamometer. Notwithstanding a slight contraction of the engine, the lamps burnt very well, as the Pilsen lamp carries 30, and some then 25 up to the last. Messrs. Woodhouse and Rawson also showed some of their microscopical and surgical lamps, in from a small battery, together with Clark's apparatus for lighting gas by electricity, and other novelties.

An electric lighting installation was last week started at the yard of Messrs. Swan and Hunter, Shipbuilders, Wallsend. It consists of one Crompton-Burgin dynamo machine, and six arc lamps for ordinary power each. The lamps are of the double differential type with two sets of carbons. The machine is driven by one of Marshall's six horse-power Compound engines fitted with Hartnell's automatic governing gear. The installation was carried out by Mr. Wilson Hartnell, of Neville-buildings, Leeds, who it will be remembered was also connected with the lighting at the Leeds Town Hall, which proved such a success.

The subject of electric lighting was also under consideration last week by the Dundee Gas Commissioners at their monthly meeting, a report having been submitted by the Finance Committee in reference to the "Electric Lighting and Power Company of Scotland." By the terms of an agreement entered into with the Gas Commission the company were bound to deposit a certain sum of money, and that lastly as a guarantee for the due performance of the contract to proceed with the lighting of a certain portion of the town in accordance with the terms of the provisional order obtained by the company. But the company are now liquidating, their business in Scotland having been so small and unremunerative; and on the recommendation of their Finance Committee the Gas Commission have resolved that no claim be made upon the liabilities of the company for the costs incurred in connection with the provisional order. In connection with this matter it may also be stated that public lighting under the Electric Lighting Act seems to have made no practical progress in any of the large towns throughout Scotland. The municipal authorities of Greenock have marked out a portion of the town in which they intend to provide the electric light for such of the householders within that area as may wish it; but up to the present it is their intentions, rather than their practical efforts, that have to be spoken of, the latter being still in the future.

Messrs. J. Holmes and Co., electric light engineers, of Wortington-road, Newcastle-on-Tyne, have lately completed a very satisfactory installation at a new and recently opened Wallsend-on-Tyne. The plant comprises two dynamo-electric machines driven by means of a six horse-power Tangye engine provided with a high-speed Pickering governor. The dynamos, and furnishes the requisite current for sixty Swan lamps, arranged mostly en clusters of four electric lights. Around the windows of the cafe there runs a massive tube carrying 41 intervals fifteen special brackets together with gas jets, so as such as the only morning when the machinery is not running. On the outside of the building are placed two arc lights supported by hinged brackets capable of being swung round in front of a window, for the purpose of removing the carbons, &c., without the use of ladders or bending apparatus. Arrangements are made for hanging one of the lamps when required in the concert hall, and also for using it to work a magic lantern for illustrating lectures. Amongst the novelties of this installation may be mentioned a new arrangement by which the electric current is utilised for the simultaneous lighting of the arc burners in the ceiling of the concert hall; this is done by small coils of platinum wire, the hour each burner which are rendered incandescent as the circuit being completed through them on pressing a push.

There has recently been an exhibition, at 21, Austin Friars, E.C., of a primary electric battery, invented by Mr. C. C. H. Rose, and offered for sale as an agent for electric illumination of all kinds. The two electrodes are zinc and copper; the former is surrounded by an acidulated solution of common salt, and the latter by a depolarising solution, the nature of which is kept secret. Each cell measures 15 in. by 12 in. by 4 in. outside, and contains three zinc and two carbon plates. These cells are coupled in series to obtain the necessary electromotive force for driving the lamps, according as they are designed to be fed with currents of 30, 45, 60, and 100 volts. The electromotive force of each cell is slightly under two volts, so that for 100 volt lamps there are required about 49 cells, so owing to their internal resistance, the difference of potential at the terminals falls below the theoretical amount. Of course the discharge of the battery vary with the number of lamps to be fed, as in the case of the arm mentioned above being capable of supplying about 20 lamps of 20-candle power. If the lamps be increased, larger cells must be used, or two cells be coupled parallel. It is stated that the Rose battery has a large working capacity, remaining constantly below the maximum for 12 hours, without sensible falling off in the intensity of the current, and then all that is required is that a small portion of the depolarising liquid should be added to the cells and the cells filled up with an equal quantity of fresh solution. Mechanical arrangements are provided whereby this can be done with ease and rapidity. The inventor affirms that the working expenses of his battery do not exceeds per electrical horse-power per hour, or rather less than one halfpenny per hour for 2 hours of lamps.

Hitherto the question of dealing with electric lighting matters in Glasgow by the public authorities has been left very much in the hands of the Corporation Gas Committee, but there are indications now that such matters will henceforth be relegated to the care of the Town Council proper, or to the care of that body in the capacity of Police Board. Referring to that subject at last week's meeting of the Town Council, Bailie Richmond remarked that the question of electric lighting for the city was a very important one, and one that would force itself upon them, whether they were willing to carry it out or not. His opinion was that they ought to have an independent committee of the Town Council. Mr. W. R. W. Smith said he would support Bailie Richmond in the remarks in that direction, as he was perfectly certain that the electric lighting question could not possibly be fairly considered in the Gas Committee. Electric lighting was a question by itself, and one requiring special knowledge. Bailie Richmond stated that he was quite prepared to move for a committee, but in the first place he wished to have an indication of the Lord Provost's opinion on that point. Dr. Marwick then spoke, replied by saying that the question to be decided there was whether they were to carry the matter to the hands of the Gas Committee, or whether it should be taken out of their hands and dealt with separately. He was to be taken out of the hands of the Gas Committee, it must be dealt with not by the Town Council, but by the Police Board, under the Act of Parliament. He would not like to say definitely what course should be adopted until he had had an opportunity of looking more fully into the matter, and therefore he suggested that it should be delayed in the mean time. Bailie Richmond then gave notice that he would bring up the matter again on the 7th proximo. Dr. Marwick had given his opinion.

An interesting action at law connected with electric lighting has lately been tried in the Court of Session at Edinburgh before Lord M'Laren, when a case was raised by Mr. A. H. Dodgson, London, against Mr. Wm. C. Main, of Inistrynich, Argyllshire, to recover payment of the sum of 2100, 10s. in respect of the Dodgson apparatus for lighting Inistrynich House by electricity. The pursuer had furnished defendant with an estimate for the apparatus and placed between the parties at a price not exceeding 2237. The pursuer supplied the apparatus and performed the necessary work, which, it was alleged, was completed by the 15th September 1882. The account amounting to 2100. 12s., payment of which was refused by the defender, and in consequence the action was raised. The defender averred that the work was not taken by the pursuer but not yet been completed; that the work hitherto executed by the pursuer had not effected the intended purpose; and that in point of fact his house was not yet lighted by means of electricity. The pursuer averred that if the apparatus was now lighted, the inefficiency was owing to the defender having discouraged the lighting, and interfered with and damaged a part of its work. Proof was led some time ago, and after judgment, Lord M'Laren decided against the defender for the sum sued for and expenses. His lordship said it was a matter of public notoriety, at the time when the contract was entered into, that the lighting by means of electricity was in an experimental stage. Mistakes in the execution of such a contract were almost unavoidable, and therefore excusable. The defender found fault with the lamps, but it had been proved that they had been obtained from the eminent firm of Siemens, and not procurred there, and it was difficult to see how the pursuer could fulfil his engagement, except by applying to the best manufacturers in the trade. The system would have worked well had it not been that the dynamo machine was, for some reason or other, not driven at a uniform rate of speed. He was of opinion that the pursuer's work was scientifically correct, and well executed.

Science N. Y. July 1883.

THE EDISON LIGHT.

A gas lighting and sanitary journal published in London asserts that Mr. Edison has thrown up his electric light researches, and left for California, and suggests that there is now a fair field to those disposed to try their hand in this direction.

Possible the *"wish"* was father to the *"thought"* with the promoters of this journal, when they printed this atrocious statement, which is not only false but malicious.

In this country a contradiction of such a *"canard"* is, of course, unnecessary. Mr. Edison has ceased to notice attacks of this nature, and possibly in his retirement at Menlo Park, and with every moment occupied on his important work, he may not even know of them. Warned by experience of the misinterpretation placed upon his willingness to permit the public to witness the gradual progress he was making with his carbon-electric lamp, he has of late discouraged the continued reporting of his movements, but within a very few weeks a whole section of Menlo Park will be illuminated by means of his carbon-electric light, equal in extent to one of those districts which will be afterwards established in New York City if success is achieved.

When the arrangements are completed the question of the success or non-success of Mr. Edison's system of electric lighting will be removed from the arena of experimental demonstrations. Here will be an exhibition on a full-sized scale, which must be decisive, as accurate calculations can be made, and every point determined down to the smallest detail.

This will be Edison's answer to all the unscrupulous arguments and scientific hair-splitting which has been of late, with such persistency, carefully disseminated to his disadvantage. Taking the view that it is a waste of time to argue theoretically, on that which can be demonstrated practically, Edison, through all this struggle has been silent, but not idle; while others *talked*, he has *worked*, and in a few short weeks all will be ready, when those who are competent can see and judge for themselves.

In the mean time, during this short interval, let slander be silent. The public is becoming nauseated with the worrying cry of *"new discoveries,"* and the real men of science in this country, appreciating the true scientific course Edison has followed to solve the question, are prepared to give his results a crucial but fair investigation.

The Lyell Mechanical Mews
Ohio, July 25, 1887.

THE MARCH OF THE ELECTRIC LIGHT.

DISAPPOINTMENT has sometimes been expressed by impatient or over-sanguine persons, at what appears to them the slow development of the new method of illumination. There are numbers of people who expected lone before this to see the gas-jet ignominiously turned off in every house, the street lamp-posts degraded to newspapers for loiter-boxes, and the gas companies overwhelmed with ruin, or proclaiming a miserable existence here and there on an unexpected and limited scale. So rapid is the spread of information in these days, so quickly is every new idea seized upon, analysed and applied by thousands of busy hands and brains, that no sooner is an improvement or discovery of any kind announced than we look at once for its perfect success and universal adoption. In former times people disbelieved and waited, and at last were slowly and reluctantly convinced. Now we have gone to the opposite extreme, and fallen into the habit, to use a commercial term, of discounting at once every promise of scientists and inventors. The wonderful facilities we enjoy have bred a corresponding impatience. Flying across the country at the rate of thirty miles an hour, we grumble because it is not forty or fifty. It is not very long since the telephone became a thing of daily use in our large towns, and we speak of it with the unfortunate instrument gets an exasperated twitch if the business which last year would have taken half a day can not be transacted in two minutes.

The electric light is surely coming; but Nature does not part with all the details of a valuable secret at once. There must be many trials, repeated experiments, modifications and adaptations before the new agent will be fully conformed to the necessities of the case. With certain uses of the new light the public is already familiar. Its power and effect in the illumination of large spaces are sufficiently proved, and have been witnessed by multitudes in London, New York and Cleveland, at Niagara Falls and many other places. The city of Akron, Ohio, has tried the experiment of lighting its whole area from lofty towers or "masts," and the result is reported as highly satisfactory. Many large breaches in different parts of the country, chiefly those of manufacturing establishments, have for some time been illuminated by electricity. Among the most recently recorded indications of progress is the introduction by Mr. Edison of his "tubular electric light," in a house on Fifth avenue, New York City. The experiment seems to have been a remarkable success. The New York Sun says that "a more brilliant and a steadier light could not be desired. There is none of the flicker so frequently observed in some of the electric lights, and which also characterizes gas-light; but the incandescent horse-shoes glow with a quiet and steady intensity. The electric current is turned on and off, like gas, and the instant pressure is put in upon the carbon it becomes brilliant. No more convenient light, therefore, could be had. No match is required to ignite it. It is clean, odorless and almost without heat. The hand may be pressed against the glass bulbs, inside of which the light glows, without discomfort."

Of the comparative merits of the several systems of electric illumination—notably the Brush, the Weston, the Edison and the Jablochoff methods, so named from their respective inventors—the world has yet to remain open to conviction. Three different systems were recently tried on a large scale in London, but the conclusions reached are not yet fully known, though the practical value of the light is said to have been clearly demonstrated. An objection which has often been made to it, namely, that its intense brilliancy is trying and hurtful to the eyes, is believed to have been removed by the latest modifications of the current, and the suggestion has been made, with much apparent reason, that if people were to gaze at any other light, whether at a gas-jet or a coal-oil lamp, with the same fixed stare which curiously leads them to direct at the electric light, they would find the effect scarcely less injurious.

We have abundant faith that the problem of the electric light, both for public and household use, will be worked out. The man who said a year ago, "The days of the gas companies are numbered," may have been prematurely wise. The first feeble attempt to operate a railroad did not at once bring all the owners of stage coach lines upon public charity, and we doubt not the holders of gas stock will find in some way an equally gradual and happy release. So great a blessing to mankind as a perfect illuminating agent can not be doomed to failure on the very eve of success. Not to reach the goal so nearly won would be as if Columbus, when in sight of land, had turned back unbelievingly from the New World, and no brother navigator had ever completed his work and redeemed his failure.

BLEACHING BY THE ELECTRIC LIGHT.

A process has been devised for bleaching blood albumen by means of the electric light. The albumen is taken after separation, and either before or after drying. It is then exposed to the light. The inventor arranged electric lights fitted with lenses or reflectors, so as to cast their light upon the albumen which is to be bleached. If it is still liquid the light is thrown upon the plates or trays which contain it in the drying stove. These plates may be made of glass, so as to let the rays pass through them. If the albumen is dry the light can be thrown upon layers of the article arranged upon the stage. In either case the process varies in duration, according as the albumen has been more or less completely separated from the clot. Under ordinary circumstances twenty-four hours will suffice to bring about a perfect decolorization. For more efficacy the electric light may be brought into action at the beginning of the process, when the clot and the albumen are being separated.

vested interests, the great railway companies, are required.

Last year there was some indication that Parliamentary Committees were inclined to view with approval the claims of independent companies to establish themselves in districts hitherto ruled over supremely by great companies, and in view of this these latter put forth all their strength, and much money in defense of their monopolistic rights, to crush the invaders of their monopolies. The Bill for the Barnsley Railway was enabled to triumph over the opposition, supported as it was by nearly all the eminent engineers of the day. In the same session, Newbury, and Southampton schemes was passed. This was, for the most part, only a revival of a railway the Act for which was obtained in 1873, with certain additions that converted it into a practical and valuable scheme, but which mixed up a determined opposition, led by Sir Edmund Beckett and supported by Mr. W. H. Barlow, then president of the Institution of Civil Engineers, on the part of the London and South-Western Railway Company, into whose domain it was supposed to intrude. Again, the Liverpool and Birkenhead Railway Company was enabled to obtain an Act for their incorporation in spite of the efforts of the Mersey Railway Company, which had been, during fifteen useless years, in Parliamentary progress of the locality.

When the results of similar applications in former sessions are recalled, this change in the views of Parliamentary Committees is brought into striking relief. For example, some twenty years ago an independent line, then called the Doncaster and Wakefield Railway, was promoted to supply an important link in the communication between Leeds, Bradford, and London. This was brought forwards for two or three sessions but finally was authorized under the name of the West Riding and Grimsby Railway in 1862. Five years later this line gave up its independence, and became the joint property of the Great Northern and Manchester, Sheffield, and Lincolnshire Railways.

Perhaps the last state of this line found some influence in the deliberations of committees, when in later years had to consider application for new lines of an aggressive character, for there were many notable instances of the success of schemes either starting under joint auspices or adopting a hybrid state in their course through Parliament.

Such was the case with the Manchester and Liverpool joint line of the Manchester and Sheffield and Lincolnshire, Midland, and Great Northern Railways, with the Leicestershire lines of the Great Northern and London and North-Western Railways which were granted in 1871, though the latter has since blended itself with that of a scheme by the Midland, rejected in the preceding session. The most notable instances, however, was probably that of the amalgamation of the rival schemes of the Great Northern and Great Eastern Companies in Lincolnshire in the session of 1873, as well as making Acts for long lengths of line at either end of those specially sanctioned in that session.

To return to the present session and its peculiar feature, the scores of Bills for railways indepen dently promoted.

The passing by the Commons' Committee of the independent line between Uxbridge and Rickmansworth, and the rejection of the Great Western scheme for the same route has been referred to already (see page 491). What the fate of the one survivor will be when it comes before the Lords, is of course uncertain, though the chances appear to be in favour. The Swindon and Cheltenham Railway, which was successfully and powerfully opposed by the Great Western Railway Company, has nevertheless gained a signal victory, and the future proceedings of this line will present an interesting study. It is a struggle for complete independence from an Act of Parliament to a completed line successful, it is to be hoped, in working and satisfactory in its accommodation. The two rival schemes for the accommodation of the district between Ballymena and Belfast, promoted, one by a narrow gauge independent company, and the other by the Belfast and Northern Counties Railway, have met with an uncommon reception in the Lords; the preambles of both Bills have been proved. Some modification will, of course, have to be made, as the construction of two lines to accommodate the same comparatively unimportant district is highly improbable. Belfast has been quite a centre of interest in a small way this session, for not only have the promoters been successful in the case of the Bills just mentioned, but the preambles of the Belfast Strand Town and Holywood Railway has been passed by the same committee. This line will provide accommodation for a large residential district on the south side of Belfast, at present only imperfectly served by the Belfast, Holywood, and Donager Railway, which pursues its course at a low level along the shore of Belfast Lough; it was constructed almost thirty years ago, and is alleged to be insufficient for the traffic and awkward of access. Application had been made unsuccessfully in previous sessions for powers to construct this line.

The Lords have also passed the preambles of the Seacombe, Hoylake, and Deeside Railway, a line which has for its object the conversion of the residential district served by the Hoylake Railway with Seacombe, and by means of the ferries from that point to join with Liverpool. The Hoylake Railway extends across the northern end of the peninsula between the Mersey and the Dee, from the western end of Wallasey Pool to Hoylake; from Wallasey Pool to Woodside there is a transway, but on account of the many breaks in the short journey between Liverpool and Hoylake via Woodside ferry, it has proved unsuccessful.

The great fight between the promoters of the Guildford, Kingston, and London and the London and South-Western Railways for power to make new lines in Surrey has ended in a compromise, under which the line from Fulham to Surbiton is to be joint property of the two companies, and the railways traversing the remainder of the county in dispute are to be in the hands of the South-Western Company. This will no doubt be satisfactory to the district Council, who are supporting the Bill for the Guildford, Kingston, and London line, over the proposed railways in the richest and probably the only part of the district it will open, and to many of the chief wants of the inhabitants of Surbiton, who are the most numerous and influential supporters of the Guildford line. On the other hand, the London and South-Western Railway Company may congratulate themselves upon having restricted their opponents to the confines of their territory and probably prevented in anticipation the success of any future schemes which may attempt to cross their lines into the heart of Surrey. The people of Guildford are hardly satisfied with this arrangement, however, which, though it gives them access to London in a certain quarter, hardly relieves them of the grievances they complained of.

The preamble of the Oxford and Greenbridge Railway was shorn of some of its importance in passing through the Commons' six running powers sought for to give access to London Bridge and Victoria Stations were denied, being only granted to Croydon and Tunbridge Wells; in other words, only restricted access has been given to the main lines of the London, Brighton, and South Coast system.

MAXIM'S ELECTRIC LIGHT.

THE incandescent system of electric lighting, invented by Mr. Hiram Maxim, of New York, has recently been introduced into London by Mr. N. de Kalinin, and is now being exhibited every evening at the Albany Works, 374, Euston-road. In point of steadiness and beauty it is one of the best incandescent lights yet made public.

The Maxim-Weston dynamo-electric generator resembles in external appearance, and somewhat in its internal construction, the distributor and the exciter. The exciter is a small machine for supplying the current to the electro-magnets of the distributor, and runs at about 800 revolutions per minute. The distributor which generates the working current is really a combination of two machines on the same base, and these can be joined up together so as to unite their currents in tension or in quantity. This machine runs at about 900 revolutions per minute, and many of its details are of a novel kind. This generator is known as Maxim's No. 20, and yields a single-arm light of 20,000 candles. Under the incandescent system, however, its total lighting power is considerably reduced. It is claimed to supply 85 Maxim lights of 25 candle power each, making an aggregate of 2125 candles, or 25 Maxim lights at 170 candle power each, amounting to

Of the smallness of the incandescent light over that of the arc has long been understood, but hitherto the cost of the one has been so great that practically it was out of the question for general use. This will account for the little progress made by the Werdermann light. The cost is due principally to the consumption of carbon. Again, it is well known that the consumption of carbon, in an atmosphere containing no oxygen, or in a vacuum, is reduced to a minimum. Many inventors have tried to reduce this to practice in order to produce a light which can be easily, and without much knowledge, used by surrounding the lamp with water Mr. Broughton has solved one of the problems of the incandescence lamp. The oxygen originally in the lamp globe is quickly exhausted, and then the atmosphere consists of gases which do not combine with carbon, and the result is very slow combustion or disintegration. The water-light joints have been obtained in the manner above indicated, the globe is partially filled with water, so that when placed over the lamp globe, the water is well over the cap. This water globe is fastened by means of clamps and screws. The inventor states that while the carbon burns away at the rate of six inches per hour in the open air, it burns only one-eighth of an inch per hour when in the water-covered globe. This shows an enormous saving in the cost of carbon, and if it can be shown that the saving thus obtained is greater than the cost of the extra power absorbed by the incandescent lamp over that of the arc, a decided step will have been made towards furnishing a light that can without difficulty be applied to ordinary street rooms. We have seen this lamp, and can testify as to its steady light.

So long as the liquid in the vessel is above the cap of the lamp the atmospheric air cannot enter the lamp globe, and the same atmosphere of gases is constantly carried off or dispersed and the light diffused. Provision is also made for the removal and revivifying of the liquid in or last causing it to circulate, but we are of the opinion that the preceding plan will prove more satisfactory as it is, than any addition to the apparatus can make it. We made inquiries as to the liability of the copper wedge to melt, but its size and its connection with so large and such good conductors removes all uneasiness in this direction.—*Electrician.*

A new form of electric lamp has been invented by Mr. Charles Stewart, M.A. It consists of a number of square carbon rods placed radially upon a disc of wood, or metal, in such a manner that the inner ends of the carbon rods form a complete circle. There is a circular opening in the wooden disc through which the electric light is seen from underneath. The carbons which are all forced toward the centre by a uniform pressure, move forward as they are consumed, and together form the positive electrode of the lamp. The negative electrode consists of a covered metallic physical cup of copper which before the current enters the lamp, rests upon the ring formed by the carbons. On the current entering the lamp an electro-magnet raises the negative electrode sufficiently to form a small arc between the circle of carbons and the metal electrode, the intervening space of water through the latter to keep it cool. The inventor claims for his lamp the following advantages. (1). It is automatic in its action. (2). Burns for a considerable period. (3). Throws no shadow. (4). Simple and inexpensive in structure. (5). The intensity of the light may be increased if desired.

ELECTRIC LIGHT.—The *Miller* has received from one of its correspondents particulars of the lighting of a flour-mill by electricity. The firm in question gave the order to put forty incandescent lights throughout their mills, and within three weeks from the date of order the lights were at work. The apparatus consists of a dynamo machine for working forty incandescent lamps of 16-candle power each, which are distributed about the various floors as required, and controlled with switches for turning them "on" and "off" at pleasure. From the start everything went on smoothly. During the first month a few lamps were broken, but since, on becoming more used to working the dynamo brushes, &c., the breakage is, on an average, two lamps per month. The lights have been now running for about 2,000 hours, and many of the lamps, which have been burning from the commencement, are apparently as good as ever. The dynamo, which requires about four-horse power, is driven from the mill engine, and needs scarcely any attention. The owners of the mill consider the electric light is much cheaper than gas, and certainly preferable as a means for lighting flour-mills. The lights are required for about 3,000 hours during the course of the year, and the following is an estimate of the relative cost of the two systems :—

ELECTRIC LIGHT.

The cost of fitting up the plant, about.....	£120 0 0
Five per cent. interest on outlay	£6 10 0
Ten per cent. depreciation of plant, &c.....	12 0 0
Renewal of lamps, 80 at 5s. each (much beyond what is actually required)	20 0 0
Oil, brushes, and sundries	3 0 0
	£43 0 0

GAS.

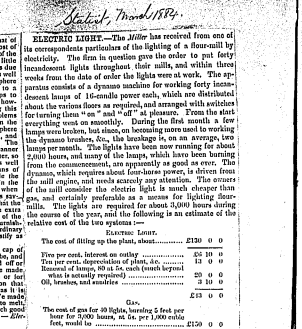
The cost of gas for 10 lights, burning 5 feet per hour for 3,000 hours, at 6s. per 1,000 cubic feet, would be £150 0 0

This leaves a balance of £107 to pay for the extra coals which may be required to generate the extra engine power necessary. It will be seen, writes the firm, that where the existing engine power can be used, the electric light is very much the cheapest method of lighting, and it has also many other advantages over gas—no heat or smell in the mill, no matches, and, as far as we can judge, perfect safety in its use and freedom from chance of fire.

THE GULCHER SYSTEM OF ELECTRIC LIGHTING.

Mr. J. G. Gulcher, of Blois, in Gallicia, is the author of a system of electric lighting, comprising a generator, a special form of lamp, and a mode of installation, which is being brought somewhat prominently under notice at the present time, and has been for some months past in actual use at the works of Messrs. A. Bateman and Co., King's-road, Chelsea. The dynamo-electric generator, illustrated by Fig. 1 on this page, is arranged with eight field magnets placed in two groups of four around a circle, four end of each being bolted to the frame, as shown, and the other ends established opposite each other. Each opposite pair of field magnets is provided with a wedge-shaped pole piece, the wider edge of which is curved, and the two are connected by a curved top plate, in the way the four pairs of magnets are coupled together, so that their pole pieces form four trough-like recesses or circle, within which the armature revolves. This is a flat ring made of iron wire, wound within the usual manner, and something like a Gramme armature, but they are not analogous, the core being separated between each coil. From the drawing it will be seen that the coils on the armature are brought within the magnetic field not only at their periphery but at its sides, so as to reduce the amount of idle coil as far as possible. A peculiar feature in the machine is that the field magnets are wound with a copper rope formed of a double strand of thick wire.

The Gülcher electric lamp, which possesses several ingenious and highly practical details, attracted much attention at the Paris Electrical Exhibition last year by the steadiness of its light. Although it does not belong to the class devoid of regulating mechanism, such as the Sedgfield, Werdermann, and others, it has no clockwork, and therefore may be used only to great advantage where necessary. It will be seen, writes the firm, that where the existing engine power can be used, the electric light is very much the cheapest method of lighting, and it has also many other advantages over gas—no heat or smell in the mill, no matches, and, as far as we can judge, perfect safety in its use and freedom from chance of fire.



thereby causing the electro-magnet to turn on the trunnions of the ring B. By this movement the lever-holder H is necessarily lifted because of the contact with the curved face of the armature A. This motion brings her smaller and more uniform than could be imparted by a rack and pinion; the two carbons are separated, and the voltaic arc produced. As the carbons burn away, and the distance between them becomes greater, the resistance increases, and consequently the strength of the current diminishes, and the piece J¹⁰ of the armature becomes further removed from the field magnets. As the carbon points approach each other, and the current continues to move on its course, the piece J¹⁰ of the armature J⁹ is arrested by the stop M, and the position of which has been carefully adjusted. As soon as this condition has been established, the magnet G has no further movement, the carbons continue to burn until they are at that distance apart corresponding to the greatest intensity of light. As soon however as further consumption increases the distance, the attracting power of the magnet G becomes too small to enable its armature to hold the bar C carrying the upper carbon, and this bar begins to slide down, until the carbons are brought nearer together, and the power of the magnet is increased so that it again holds the bar H and prevents it slipping further. If this bar continued to fall, the power of the magnet would increase until the armature J⁹ would be drawn down to the piece of iron M and the preliminary process of lighting would be repeated. In practice, however, it is found that after the lamp has been started it remains constantly stationary, the consumption of the carbons and the wear of the points being just sufficient through the intermittent motion of the magnet to secure the automatic working of the lamp. The fact of the armature J and the rod H are covered with thin tubes to diminish the retentive power of the magnet and to facilitate the sliding of the latter. The carbon-holder carrier is by a simple device that makes the action of the regulator much more sure and checks irregularity in the light. The block of iron L attached to the spring G, and acting as a stop to the armature, is covered with thin tubes as are also the armature J¹. This block serves as a brake and prevents the vibration of the electro-magnet when the lamp is started, and secures a soft and easy movement. As shown in the drawing, carbon-holders are made movable, so that the positive carbon may be kept unaltered. Another method of securing the necessary motion is shown in the drawing, where threads D, D¹—the former to the upper, and the latter to the lower carbon-holder—are wound round the drum N, both being actuated by the movement of the rod H.
